3605. Will It Work

Yahoo group: ham-antennas (2008)
Date: 2008-01-01 07:08:46 UTC
From: F5Storm
Topic: 3605 Message: 3605

Hi All

To all you antenna guru, because I have very bad earthing problem [the only way it could be worse if it was solid rock] and I only have 19Meters by 8Meters to put up an antenna for HF this rules using radials for a vertical

I was thinking of putting up a 46' dipole and center feeding with a 4: balun and using a LDG Antenna tuner, 23' is one of the optimum length or random wire antenna so instead of earthing one side of the balun I use anther 23'of wire

Do you think it will work?

73

The SWR would be awfully high on 80 or 160, but the tuner should
handle it OK in 40-6m.

3608. Flag pole

Yahoo group: ham-antennas (2008)
Date: 2008-01-05 03:12:56 UTC
From: ghostkasper
Topic: 3608 Message: 3608

I am planning to put up a twenty foot flag pole antenna in my yard (Force 12). I am thinking
of running a forty foot wire from the top of the pole to the peak of the second story of my house. The wire will be running East to West.

My question is: what kind of radiation pattern can I expect and should I still plant a radial
field?

Come on experts, give me some input. I need help to fool the CC&R police.

Thanks;
Ken, N7GH

3609. Re: home-brew in trailer park

Topic: 3592 Message: 3609

A way a friend got around a restrictive trailer park (no ant's) in Orange Co CA beach area - it was to install a flag pole.

The unique items was the flag pole was a used/cracked fiberglass mast off a sail boat - FREE for the hauling - (the hardest part was he had to cut it in half to transport then sleeve to repair). The mast is hollow core - perfect for a 80m (plus 160 coil) vertical multi-band. There was even enough room at the top to install a dual band 2m/440 J. Installed a ground rod at the bottom of the hole , PVC'ed the two coax cables from the cement base and planted the whole thing in cement.

Never had a weathering problem and as far as I know he's still using both - no one is the wiser. His +40' tri-head flag pole is the highlight of the park - sporting a USA, CA, Vietnam Vet flags. On game day he hoists a Green Bay Packer flag. This old jarhead even hoists USN signal flags making a game for all to figure them out. After some gun fire in the near area he hoisted a red burgee (dangerous evolution taking place) with two black balls flags (restricted navigation) for three days - the authorities were not to happy about that but the sailing community laughed (and ducked).

Another approach to getting on HF from a trailer park can be found at www.n8tw.com Ted has a stealth longwire on the outside of his mobile home and works all bands with it. He just used an insulated wire the same color of his mobile home and runs it around the perimeter and into the shack to an MFJ-986 tuner.

Another approach to the flagpole antenna would be to get one of the 31' telescopic fiberglas poles from Jackite - www.jackite.com and run a #14 wire up through the center and use an autotuner at the base such as the Icom AH-4. A friend of mine has done this and even uses one on his pontoon boat for 10 thru 80 meter operation. I use one for portable operations with my Icom 703 and its built in autotuner, but the 703's tuner requires the use of a unun to allow it to tune a wire on several bands. Info for theunun for the 703 can be found on my website at: www.angelfire.com/electronic2/qrp/unun.html

Hello,

I am selling my remaining Zenith Heathkit and electronics books. I could really use the money as well as clean out the house.

I have lowered the prices to $2.50 each for the Zenith Heathkit books. The general electronics books are $1 unless marked.

Please email me for more information.

Thank you!

Mitch

3612. Antenna Radial Question

Yahoo group: ham-antennas (2008)
Date: 2008-01-08 16:38:26 UTC
From: Greg DeChant
Topic: 3612 Message: 3612

I'm a newbie to all of this, so I appreciate any and all help as well as I know these questions have probably been covered else ware in the group, so I apologize for asking again.

I have a Hustler 6BTV vertical that is mounted in a very small space. At least a small space to run full length radials, in all directions, at the top band for the antenna. (80 Meters). Even with bending them around I eventually end up with them all in one direction and parallel to each other. Is this ok, or should I consider another method of running the radials away from the base of the antenna.

I chose this mounting spot because everything else was located close to our house, which is covered in aluminum siding and the many large trees, which are not transplantable. At least not transplantable within our budget.

If you like, I could draw a diagram of the mounting location and the space their in and upload it to the files section. If that would help the group to see what a tight spot I'm in.

Greg,

I am assuming this vertical is ground mounted. If that is the case, if you have enough room to lay out a bunch of radials that are the length of the antenna, that is all you will need. You can even bend those around if you have to. You will not need 1/4 wave radials for each band if ground mounted.

Thanks for the idea Patrick. Unfortunately, what I would call the back of the antenna mount is close to our wooden deck, for protection from the kids in our neighborhood that run through our yard and I don't think it is feasible?

I guess snaking them in some way is the only choice I have. But the way I would have to do it is probably going to produce a weird radial radiation pattern. Since the suggested method is to lay them out in some kind of a semi circle around the base of the antenna and that is not possible???

Hi Gene!

Yes it is ground mounted. Sorry I didn't mention that in my original post. The bigets problem, in addition to mounting it in a cramped space, is not being able to put down radials in a 360degree circle around the base of the antenna.

I would imagine that putting as many radials around the base in any direaction I can is better than having none?

I would imagine that putting as many radials around the base in any direaction I can is better than having none?[snip]

Now you've answered your own question ! With a ground mounted vertical, the length of the radials really means nothing as cutting them to 1/4 wavelength only serves to satisfy the mind because radials that are cut to frequency will be detuned when they are laid on the ground anyway. So, just install as many as you can in any way you can - all you are really doing here is increasing the ground conductivity around the base of the vertical which is where the most of the radiation comes from (high current point) and when the ground loss is decreased, antenna efficiency is increased. If you are worried about folks tripping over the radials, just pin them down with wire staples used for anchoring sod grass or you can even make your own staples by using old wire coathangers and cutting the wire into 6 inch lengths and then bend them into a sharp V shape. Lay the radials down and push the staples down over them into the ground to hold the wires flat on the ground. Use several staples along the length of each radial to hold its entire length down. In the spring when the grass grows, the radials will dissapear into the grass.

Greg, radials used for the return current, i.e., antenna current, should not be layed out in concentric rings. Radials should be "radial". Out from the feedpoint like the spokes of a bicycle, never in a circle around the feedpoint. Wires going in a circular fashion connecting the spokes do nothing for the antenna current. They may be OK for lighning grounding, but not for antenna current. My reference is W2DU's "Reflections" book.

Hi Stan!

My problem is I am not able to run my radials out from the antenna feedpoint like the bicycle spokes as you mentioned. I unfortuniately had to mount it where the is 0ft 12ft 12ft and 20ft of room on either side of the feedpoint. I am open to any and all suggestions as to how to properly run radials in this small space.

From: Gene Gabry
Topic: 3612 Message: 3621

Hi Greg,

Although your in a tight spot there, lay down as many
of any length of radials that will fit, the more the
better. You just need to improve ground conductivity.
Lots of short radials will be better than none at all.
Just put down what you have room for, and then enjoy
the bands!

From: Stan Kozlowitz
Topic: 3612 Message: 3622

Gene, You are right. And Greg: I don't think the problem is as bad as you may think. The antenna is only 24 ft tall so your ground radial system doesn't need to be as extensive as a full size monopole antenna. In fact, in looking over the 6BTV instruction manual provided by DX Engineering, you may not even need radials at all.

Put out what you can as Gene suggested. You should do fine.

73,

Stan AA5XO

While this will not hurt anything, It will not help either.
The wire would be more effective used for more radials as ispointed out
below.

Greg, radials used for the return current, i.e., antenna current, should not
be layed out in concentric rings. Radials should be "radial". Out from the
feedpoint like the spokes of a bicycle, never in a circle around the
feedpoint. Wires going in a circular fashion connecting the spokes do
nothing for the antenna current. They may be OK for lighning grounding, but
not for antenna current. My reference is W2DU's "Reflections" book.

I guess snaking them in some way is the only choice I have. But the way I
would have to do it is probably going to produce a weird radial radiation
pattern. Since the suggested method is to lay them out in some kind of a
semi circle around the base of the antenna and that is not possible???

From: Doug
Topic: 3619 Message: 3626

Hi Russ,

There's a lengthy list of antenna calculator programs written by G4FGQ on this page:

http://www.zerobeat.net/G4FGQ/page3.html#S301%22

Scroll down the list and look for one called LOADCOIL

Bookmark that list, there's some very useful programs there.

I've used LOADCOIL before and it worked very well. Winding the coil to the calculated specs put me right in the ballpark when I made a 40m loading coil for a 10 ft portable vertical.

Have fun

From: aml_stl
Topic: 3627 Message: 3627

Hi all, just starting my quest for a good HF beam for tripod mounting on the top of my home using a 6' pole for the antenna. Roof is about 21 feet above ground level.

The smaller the footprint the better (due to the tripod mount) but would like to have 40, 20, 15 and 10. I'll probably have to do without 40, but I could live with that...

I was looking at the MAB5, but would appreciate other suggestions.

Thanks.

AML

In the past I used a 2 element tri band yagi mounted at 35 feet. It
worked as well as could be expected. It was a 3 element when I bought
it. I wanted a shorter boom so the yagi would not hang over my
neigbours driveway. So I used the reflector and the driven elements at
the same spacing they originally were on the 3 element yagi.
SWR was fine, the beam still had some reflecting power and directional.

If you are using a tripod on the roof I doubt you would want to have a
yagi that is capable of 40 meters. You would be better off hanging up
a 40 M dipole.

You need a solid mount for a 3-4-5 element yagi especially if you have
high winds in your area. The last thing you need is a yagi and tripod
getting torn off your roof!

Good Luck
Rick VE3FMC

without 40, but I could live with that...

Just build a 44' rotatble dipole from aluminum tubing, center feed it with balanced
feedline and a tuner for 10 thru 40 meter coverage - works great !

There's a Yahoo group for those who are home-brewing a "hex beam". This is a two-element Yagi, with the elements bent into opposing "W" shapes. Gain is only down 0.5dB from a full sized two element Yagi, but the rotational diameter is approximately half. Construction method is to use fiberglass spreaders and wire, so they are very lightweight and low wind area. Worth homebrewing, but VERY expensive if you buy one from the manufacturer.

AML,

I might be a tad bit biased, but the MA5B is not a bad choice for your situation. I am a very happy owner of a MA5B for many years. I have operated with other small mini beams in the past such as the HF5B butternut, TH2MK3 Hy-Gain 2 element tribander, and the TH3-Jr by Hy-Gain (when it was Hy-Gain!).

The only one of those above mentioned I would shy away from in your situation would be the HF5B. It is very very sensitive to nearby metal objects and detunes very easily.

I have been able to compare the TH2MK3 side by side with the MA5B and have found those two to be practically identical in performance. The nice thing about the MA5B is you have a rotatable dipole for 12 and 17m. I have also used the MA5B on 30m with the aid of an external antenna tuner (MFJ949E) with good results. Before I put upa 3 element 6 meter beam, I added a 6 meter dipole section to the 12m & 17m element of the MA5B, and had an antenna that basicly worked from 6 through 30m.
I have been very impressed with the F/B on 20m. It is actually better than the old TH2MK3 was. The MA5B has been totally maintanence free since I put it up 5 years ago.

I have mine mounted on a 35 foot rohn tower using a medium weight rotor from Yaesu, which has operated flawless for 9 years now.

If you have any other questions about the MA5B, or any of the other antennas I mentioned, you can contact me direct.

3632. Apartment dweller - HF antenna

Yahoo group: ham-antennas (2008)
Date: 2008-01-12 14:51:34 UTC
From: Kuby
Topic: 3632 Message: 3632

Currently, I'm Contracting and living in an apartment. Of course there is no attachable antennas allowed. So I've been eying the buddy-pole concept but find it flawed right away.

This buddy-pole is directed towards bare-foot HF rigs, QRP, FD, etc. But being a flat Horizontal dipole the there will be a gross impedance coax mis-match (300 ohms to 50 ohms).

With just a lil more metal they could put the Hamstick elements at 120 degrees angle (inverted V) which has the reactance of 50 ohms. [I'm sure you see where I'm going with this.]

The super short Hamstick elements are already a significant compromise but then add this impedance mis-match and I'm not to eager to buy this dipole gizmo antenna compromise. BUT if I could get to the MFG'er and put a bug in their ear to make a same type mount for 120 degree element model ---> Well I'm up for a buy and try!

Any leads on where/who the MFG'er(s) are?

N6JSX/0

****
FYI, I bought and installed a "3/8-24 HD ANTENNA 180 DEGREE LIFT AND FOLD OVER MOUNT T203EZ" for my SUV screwdriver whip. It has been on my SUV less than 30 days and is already bleeding "rust" from the internal position spring or un-plated guts. The outside may be chromed or SS but not the guts.

Get yourself a good autotuner such as the SGC-239 or similar and put up an indoor 2 turn loop made of 300 hm TV twinlead and feed it with the tuner. Just run the twinlead around the perimeter of the room up next to the ceiling and bring the ends back near each other. Connect the top wire on one end to the bottom wire on the other end, then connect the 2 remaining ends to the tuner tru a short section of the twinlead and use it for multiband operation. I have done this from a motel on a couple of occassions with good results, and just held the twinlead up with plastic headed push pins. With a 2 turn loop that was made out of a 40' roll of the cheap twinlead from Radio Shack I was able to work 10 thru 80 meters with it ! It will also work with a manual tuner too like the MFJ tuners.

But being a flat Horizontal dipole the there will be a gross impedance
coax mis-match (300 ohms to 50 ohms). [snip]

I'm curious as to where you get a mismatch of 300 ohms to 50 ohms with
the buddiepole ? The buddiepole can be adjusted to a low swr to 50 ohms
by properly selecting taps on the coils for the band you are operating.
If properly setup, an swr of 1.5:1 or better is possible, but adjusting
it can be a bit time consuming. The 2 turn loop and tuner I mentioned in
my other post is pretty effective and fairly cheap if you use a manual
tuner which you may already have.

From: aml_stl
Topic: 3635 Message: 3635

I've got a 20+ noise (buzzine, hash, grrrrring noise) level on 80 meters and 9+ level on 40 meters when my vertical antenna (HF6V) is connected to my radio (FT-950).

If I disconnect the antenna feed line the radio goes quiet except for the normal atmospheric noise. 10/15/20 are barely affected, and UHF/VHF is not affected at all. But 80 and 40 are horrible.

Since the interference is not there without the antenna connection I'm "assuming" it's an outside source coming in through the antenna and not the house wiring or it would be there with or without the antenna connected.

We've (the electric company and I) have tried their "sniffing equipment" without success and even my tried and true AM portable radio hasn't pinpointed it. I'm sorry to say the electric company people seemed to be at a loss as to possible fixes, saying they'd "keep an eye on it"...?? They've been here 4 times - with no results over the years.

Just wondering (besides moving) if there are any 'fixes' that I could try in line with the antennas coax to try and help the problem? Would a tunale line noise filter help, although it doesn't appear to be line noise?

Everything is grounded - the antenna is grounded with 4 8ft ground rods and using 12 radials of different lengths, and the station is earth and rf grounded also with surge supressors on all equipment.

Antenna tuner is just adding another compromise on top of an already inefficient antenna buddy-pole contraption making my radio "THINK" the antenna is 50 ohms for max power out.

Your statements and question makes it obvious that you need to study antennas to obtain a clear understanding of tuners/baluns/impedance. Your statement to "adjust the traps to fix the ANTENNA input impedance" is a common misunderstanding of new generation plug&play HAMs.

Sure anything can be tuned/adjusted but is it the most efficient method of obtaining a near naturally resonant antenna operation if the input impedance is already whacked out - NO!

Tuners/baluns ONLY ADD electronic devices to the RF signal path, hence energy is wasted/attenuated in the transforming process.

Tuners ONLY make the radio happy and do virtually nothing in adjusting the antenna to resonance that gives you the most optimal efficiency!

There are some very nice reviews of the MA5B on Eham here:
http://www.eham.net/reviews/detail/340

But your biggest limiter you have is the height and closeness to the house. This will deteriate any antenna's performance.

So the rotating dipole someone else suggested may actuall worl as well under those conditions.

Antenna tuner is just adding another compromise on top of an already inefficient antenna buddy-pole contraption making my radio "THINK" the antenna is 50 ohms for max power out. [SNIP]

No one said to use a tuner with a buddiepole antenna ! If you read my post, I said adjust the antenna to resonance by properly selecting taps on the coil to adjust the swr - this "resonates" the antenna and brings forth maximum power from the radio ! Yes, the buddiepole does suffer from inefficeincy when compared to a full sized antenna, but then so does a mobile HF antenna of any kind and they are tuned to resonance in the same manner. When operating with an inside antenna or mobile antenna, then one would be a fool to expect full size antenna performance - its simply not possible ! But if you main concern is to just get on the air anyway possible, then one must learn to operate with a slight handicap - any antenna is better than no antenna ! ! !

Your statements and question makes it obvious that you need to study antennas to obtain a clear understanding of tuners/baluns/impedance. Your statement to "adjust the traps to fix the ANTENNA input impedance" is a common misunderstanding of new generation plug&play HAMs. [snip]

And who said anything about "adjusting traps" ? The buddiepole isn't a trapped antenna ! Its a short coil loaded antenna, or haven't you learned the difference between traps and simple coils yet ? Perhaps you are a "plug and play ham" ! Your attitude does nothing to help in the matter. The one that posted the question is looking for a way to get on the air with an indoor antenna because he can't put up an outside antenna. In this situation, a full size resonant antenna isn't going to fit in most cases and he must do what he has to do make do. If you can't be constructive and help in the matter, it would be wise for you to keep silent and quit the name calling !

Sure anything can be tuned/adjusted but is it the most efficient method of obtaining a near naturally resonant antenna operation if the input impedance is already whacked out - NO! [snip]

No arguement there, but again - we aren't discussing a full sized naturally resonant antenna are we ? We are discussing an indoor covert antenna that must be forced to work regardless of its size.

Tuners/baluns ONLY ADD electronic devices to the RF signal path, hence energy is wasted/attenuated in the transforming process. [snip]

You guys with the "tunerphobia" never cease to amaze me with your "antituner philosphy" ! If you are losing/wasting power, its because you are using an inefficient system to begin with. If you strive to

eliminate system losses, then a good multiband antenna/tuner combination can be made to be even more efficient than a coax fed resonant antenna ! I've used antennas both ways and the antenna system/tuner combo I am using right now will beat the resonant antenna system I once used hands down every time !

Tuners ONLY make the radio happy and do virtually nothing in adjusting the antenna to resonance that gives you the most optimal efficiency! [snip]

Well, I see you need to study antennas more ! Give me a good tuner and low loss antenna system anyday and I'll be making contacts while you are trying to adjust your antenna to "natural resonance" ! A good balanced tuner such as a link coupled tuner or Zmatch tuner and a doublet fed with low loss balanced feedline will show an increase of about 15% efficency over a dipole of the smae size that is fed with coax. On its second harmonic it will be about 25% more efficient, so what does having an antenna that is resonant on one band have that a good tuner/antenna system doesn't ? Go back to class, you've got more to learn !

When I first got my hf rig up and going, I had a crippling splatter noise on 40 and 80 meters. My rig is powered by an Astron RS20-BB, basically an RS20 with a battery backup. Turning off the Astron did nothing to clean up the signal, but killing the ac to my house and running from straight dc power made a world of difference.

Knowing the noise was coming from within my house, I started shutting off breakers until my splatter was gone. After determining which circuit the noise was coming from, I started unplugging items. My problem was a power supply for my digital camera dock.

By hooking up to a battery and snooping around a bit, maybe you'll have some good luck, like I did.

AML - You have probably already looked at something this simple but
I have to ask - do you have or your neighbors have any lamp dimmers?
I had a similar problem I fought on 80 meters and one night I heard my
wife walk across the floor upstairs and presto!! the noise died!! I rushed
out of the basement asking what did you just do? She was about half
scared of me there for a minute but she had simply turned off the dimmer
switch. Sure didn't take long to get a new click switch put in there. I also
remember years ago (my first rig) was a Heathkit SB-104-A that I had built,
and it was horribly noisy on 40/80 but was good on other bands - Whilst
fiddling around one late night I adjusted the NB board (Duh) single pot
and it just dropped the noise completely and there were lots of folks setting
there visiting on that band - Don't guess you have one of those do you?
Good Luck & 73 should I show my call here?

my problem was an incredibly cheap, noisy power supply in my main computer. I swapped in a better unit and the noise went away completely.

There was noise all over HF, but it never bothered VHF/UHF.

Keep killing power to things until the noise goes away.

Good going your plug&play CB knowledge NEVER ANSWERED my question.
You just hijacked the subject to try and impress. bye

[snip]

Well, CB knowlege or not, while you are worrying about getting on the air, I'll be on the air enjoying my antenna that is working very well even though its not "naturally resonant" ! Hope you figure it out OM - I tried to help, and can't help if you won't listen !

And if all you want is a "naturally resonant" antenna, then forget about operating with an "apartment dweller" antenna - oil and water don't mix !

Have a great day.....

Kuby,
Your statement about the traps is correct, but your statements about a tuner are misleading , at best. A tuner that can achieve a 1:1 SWR at the radio does transform the impedance to 50 + j0 at the radio. And there is SWR on the feed line and antenna. But keep in mind that any reflected power coming back from the antenna will get RE-reflected back down the transmission line towards the antenna So, if 20 watts of power (out of 100) is reflected back toward the tuner, the tuner creates a conjugate match re-reflecting the power AND adding in-phase the reflected power with the original incident power. Now you have 120 watts of forward power. Twenty watts again gets reflected but the original 100 watts gets transmitted by the antenna, no matter what the SWR if the matched line loss is low..

Saying that tuners "ONLY" do this or that is not showing the whole picture. Tuners allow one to operate one antenna over multiple bands. And where there is SWR, the most important factor in transmission line loss is in the matched line loss of the transmission line itself.

Newbies need to learn the facts as they exist. Not old wives tales and mis-guided information.

Do yourself a favor and read Walt Maxwell's treatise on transmission lines and antennas at http://www.w2du.com. It's good reading every ham should read.

Really 73,

Kuby <n6jsx@...> wrote:
Antenna tuner is just adding another compromise on top of an already inefficient antenna buddy-pole contraption making my radio "THINK" the antenna is 50 ohms for max power out.

Your statements and question makes it obvious that you need to study antennas to obtain a clear understanding of tuners/baluns/impedance. Your statement to "adjust the traps to fix the ANTENNA input impedance" is a common misunderstanding of new generation plug&play HAMs.

Sure anything can be tuned/adjusted but is it the most efficient method of obtaining a near naturally resonant antenna operation if the input impedance is already whacked out - NO!

Tuners/baluns ONLY ADD electronic devices to the RF signal path, hence energy is wasted/attenuated in the transforming process.

Tuners ONLY make the radio happy and do virtually nothing in adjusting the antenna to resonance that gives you the most optimal efficiency!

No one said to use a tuner with a buddiepole antenna ! If you read my post, I said adjust the antenna to resonance by properly selecting taps on the coil to adjust the swr - this "resonates" the antenna and brings forth maximum power from the radio ! Yes, the buddiepole does suffer from inefficeincy when compared to a full sized antenna, but then so does a mobile HF antenna of any kind and they are tuned to resonance in the same manner. When operating with an inside antenna or mobile antenna, then one would be a fool to expect full size antenna performance - its simply not possible ! But if you main concern is to just get on the air anyway possible, then one must learn to operate with a slight handicap - any antenna is better than no antenna ! ! !

Your statements and question makes it obvious that you need to study antennas to obtain a clear understanding of tuners/baluns/impedance. Your statement to "adjust the traps to fix the ANTENNA input impedance" is a common misunderstanding of new generation plug&play HAMs. [snip]

And who said anything about "adjusting traps" ? The buddiepole isn't a trapped antenna ! Its a short coil loaded antenna, or haven't you learned the difference between traps and simple coils yet ? Perhaps you are a "plug and play ham" ! Your attitude does nothing to help in the matter. The one that posted the question is looking for a way to get on the air with an indoor antenna because he can't put up an outside antenna. In this situation, a full size resonant antenna isn't going to fit in most cases and he must do what he has to do make do. If you can't be constructive and help in the matter, it would be wise for you to keep silent and quit the name calling !

Sure anything can be tuned/adjusted but is it the most efficient method of obtaining a near naturally resonant antenna operation if the input impedance is already whacked out - NO! [snip]

No arguement there, but again - we aren't discussing a full sized naturally resonant antenna are we ? We are discussing an indoor covert antenna that must be forced to work regardless of its size.

Tuners/baluns ONLY ADD electronic devices to the RF signal path, hence energy is wasted/attenuated in the transforming process. [snip]

You guys with the "tunerphobia" never cease to amaze me with your "antituner philosphy" ! If you are losing/wasting power, its because you are using an inefficient system to begin with. If you strive to eliminate system losses, then a good multiband antenna/tuner combination can be made to be even more efficient than a coax fed resonant antenna ! I've used antennas both ways and the antenna system/tuner combo I am using right now will beat the resonant antenna system I once used hands down every time !

Tuners ONLY make the radio happy and do virtually nothing in adjusting the antenna to resonance that gives you the most optimal efficiency! [snip]

Well, I see you need to study antennas more ! Give me a good tuner and low loss antenna system anyday and I'll be making contacts while you are trying to adjust your antenna to "natural resonance" ! A good balanced tuner such as a link coupled tuner or Zmatch tuner and a doublet fed with low loss balanced feedline will show an increase of about 15% efficency over a dipole of the smae size that is fed with coax. On its second harmonic it will be about 25% more efficient, so what does having an antenna that is resonant on one band have that a good tuner/antenna system doesn't ? Go back to class, you've got more to learn !

From: QRP_1@juno.com
Topic: 3632 Message: 3646

Kuby,
OK, In reading your post, I fail to see what the actual question is ? So I'll try to get some info from you about the original post which I have included below.

Currently, I'm Contracting and living in an apartment. Of course there is no attachable antennas allowed. So I've been eying the buddy-pole concept but find it flawed right away.

This buddy-pole is directed towards bare-foot HF rigs, QRP, FD, etc. But being a flat Horizontal dipole the there will be a gross impedance coax mis-match (300 ohms to 50 ohms). [snip]

OK, first, the Buddiepole as I remember is rated for up to 150 watts, and yes it will work quite well for FD & QRP operation. If you plan on operating from an apartment that allows no outside antennas, then why would you be worried about the antenna only being able to handle a maximum of 150 watts - surely you don't plan on running more than that with an indoor antenna ? Talk about TVI?RFI - whew ! And I'm confused as to where you get the idea that the Buddiepole would be anywhere near 300 ohms ? A short loaded antenna would be more like 20 to 25 ohms at best at resonance. If it were a vertical, this could very easily be overcome by using a shunt matching coil at the feedpoint to bring it to 50 ohms after the resonant point is found. But since it is a horizontal dipole configuration, Budd has compensated for this by allowing different setting for each half of the antenna to basically make it an off center fed dipole to bring it closer to 50 ohms. FYI, I'm not deffending or promoting the Buddiepole but it is a good system - a little pricey in my book, but still a good system none the less ! So, where do you come up with the 300 ohm figure that you stated ? Please explain ? Remember, a full size dipole will be near 50 to 70 ohms depending on height above ground - no where near 300 ohms.

With just a lil more metal they could put the Hamstick elements at 120 degrees angle (inverted V) which has the reactance of 50 ohms. [I'm sure you see where I'm going with this.[snip]

50 ohms might be close to right for a full size dipole, but the Hamsticks are still nothing more than short loaded antennas and will still exhibit a low impedance. Probably on the order of 12 to 20 ohms for the Hamsticks depending on which band you choose regardless if they are mounted horizontal or inverted V style.

The super short Hamstick elements are already a significant compromise but then add this impedance mis-match and I'm not to eager to buy this dipole gizmo antenna compromise. BUT if I could get to the MFG'er and

put a bug in their ear to make a same type mount for 120 degree element model ---> Well I'm up for a buy and try! [snip]

If must have one, a dipole fixture where the Hamsticks are at 120 degrees to each other would be very simple to fabricate even without special tools. Some aluminum barstock, a drill, a bench vise, and the antenna mounts would be all that was needed. But I guarantee that the Hamsticks are going to be a compromise antenna no matter what you do. They will work, but they will be much more compromised than any simple wire that is much longer and connected through a tuner to provide the match. The bottom line is, any short loaded antenna is a compromise. A full size dipole is a compromise if its too low to the ground, but it will still beat the Hamsticks easily.

Why don't you tell us what your intended expectations are and tell us a little about your apartment setup. That way we can really figure out what you need and get you pointed in the right direction. What radio and power level do you intend to use ? What bands and modes ? I have operated HF from places where folks said it couldn't be done - even operated 160 meters effectively from a motel room with no more than 50 watts ! I've operated 80 thru 10 meters from a 14' johnboat. I've worked 15 thru 60 meters effectively @ 10 watts with a 3' diameter homebrew magnetic loop made of RG8 coax while out hiking in the woods, and even worked Australia with 10 watts on 40 meters with a homebrew vertical. I've also worked several countries with transmitters and receivers I built from scratch, so what you call "plug and play ham" doesn't apply here ! Oh yeah, I didn't have to get on a list an ask folks how to do it either - I figured it out on my own as I went along ! I will admit that I started out on 11 meters though - but that was long before I even knew amateur radio even existed ! My first CB antenna was a homebrew endfed halfwave, and the radio was an old tube rig that didn't even work when I got it - thats how I learned about tracing circuits and reading schematics back when I was about 13 years old in 1970.

3648. difference between 2el and 3el yagi

Yahoo group: ham-antennas (2008)
Date: 2008-01-13 04:25:16 UTC
From: aadu.adok
Topic: 3648 Message: 3648

hello,

I'm about to build a 15m yagi. Since my space is limited, I'm not sure whether to do 2el or 3el. Well, books say that average 2el yagi-s gain is around 4dBd, and 3el gives you 5-6dBd of gain.

Now I wonder, how big is the difference in real life? I know that we are somewhere near the solar cycle minimum, but will I be able to hear VK-s from NE europe with 2 or 3 element beam on 15m? At least I can't receive them on my G5RV. Or let me put it this way - what's the minimum antenna to hear VK-s on 15m in europe (with current solar flux of 76)?

Any thoughts, please.

Subject: Re: [ham-antennas] Apartment dweller - HF antenna

Get yourself a good autotuner such as the SGC-239 or similar and put up
an indoor 2 turn loop made of 300 hm TV twinlead and feed it with the
tuner. Just run the twinlead around the perimeter of the room up next to
the ceiling and bring the ends back near each other. Connect the top
wire on one end to the bottom wire on the other end, then connect the 2
remaining ends to the tuner tru a short section of the twinlead and use
it for multiband operation. I have done this from a motel on a couple of
occassions with good results, and just held the twinlead up with plastic
headed push pins. With a 2 turn loop that was made out of a 40' roll of
the cheap twinlead from Radio Shack I was able to work 10 thru 80 meters
with it ! It will also work with a manual tuner too like the MFJ tuners.

Subject: Re: [ham-antennas] Noise -

When I first got my hf rig up and going, I had a crippling splatter noise on 40 and 80 meters. My rig is powered by an Astron RS20-BB, basically an RS20 with a battery backup. Turning off the Astron did nothing to clean up the signal, but killing the ac to my house and running from straight dc power made a world of difference.

Knowing the noise was coming from within my house, I started shutting off breakers until my splatter was gone. After determining which circuit the noise was coming from, I started unplugging items. My problem was a power supply for my digital camera dock.

By hooking up to a battery and snooping around a bit, maybe you'll have some good luck, like I did.

3651. Re: difference between 2el and 3el yagi

Yahoo group: ham-antennas (2008)
Date: 2008-01-13 08:44:06 UTC
From: wd4elg_base
Topic: 3648 Message: 3651

Answer on the minimum antenna to hear VK's from NE Europe...it depends. On a lot of things.

Sorry, but there are many factors. How high is the antenna? Is anyone on the band when it is open? It is my experience that there is not a lot of activity on 15 meters at this low point. Even if the band is open, not many hams aware of that fact. Exceptions are during the contests. And, if you can hear them...will they hear you? More questions: how much power are you using? CW or SSB?

For simplicity, let's assume the G5RV has the same gain as a dipole. The yagi with the extra gain gives much better directivity over the G5RV and rejection of signals not in the desired direction (I am sure you already know this). Some models and texts state 4db versus 6db of gain between 2 elements and 3 elements, but this is not even an S unit. So if you can't hear them on the 2 ele yagi, you probably won't hear them on the 3 ele yagi either. If you can hear them on the 3 ele yagi, you will probably hear them on the 2 ele yagi.

So, when the band IS open on 15, why bother with a 3 element yagi over a 2 element design? Much better front-to-back ratio, in addition to some gain. Why NOT go with 3 elements? Cost, space restrictions, weight (like for 40 or 80 meters).

http://www.cebik.com/yagi/3lyg1.html
<http://www.cebik.com/yagi/3lyg1.html>

http://en.wikipedia.org/wiki/Yagi_antenna
<http://en.wikipedia.org/wiki/Yagi_antenna>

http://www.arrl.org/tis/info/pdf/7201036.pdf
<http://www.arrl.org/tis/info/pdf/7201036.pdf>

http://www.arrl.org/tis/info/pdf/8108032.pdf
<http://www.arrl.org/tis/info/pdf/8108032.pdf>

Let's take a look at a different scenario - 40 meters. A shortened vertical will do the trick from EU to VK here (I hear EU working VK every day at the same time, about sunrise for EU/sunset for VK on 40 CW. I can hear both stations on my vert, and work both from my QTH as well. I know they are also working each other). What is the key here? Not just gain, but angle of arrival. The ARRL Antenna Handbook discusses this extensively. It's not just the gain, but the angle of the maximum radiation which is important. Verticals don't have gain (at least not a single vertical by itself), but they DO have low angles of radiation. (Of course, the reason I can hear EU and VK at the same time is that verticals are omnidirectional). Why not use a vert on 15? Well, you

could. The low angles will be there with the vertical, but the gain won't...and on the higher HF bands the gain is really important because of the MUF frequency being so close to 15 during daylight.

Most importantly, make sure you get the antenna up...generally higher is better. Here is a good snapshot that is similar to the ARRL Handbook on angles of arrival. Higher is better, but shorter range DX (Africa) may suffer.

http://www2.arrl.org/FandES/field/regulations/local/antplnr.pdf
<http://www2.arrl.org/FandES/field/regulations/local/antplnr.pdf>

So, my informed *opinion* (not the absolute answer) is:

* If you can afford 3 elements and you have room, then definitely go for it.
* Get the antenna at least a half wavelength high. For the EU-VK propagation, it will have to be higher than that! Get it as high as you can.
* Look at some of the propagation models to see the best times to work VK from EU on 15. Watch the DX clusters to see when others are working VK.
* See if you can set up a sked with somebody in VK.

It is 3:30 AM local, so I am rambling. I hope I am helping you. I am sure others will be able to share much more good info that will help you as well.

This antenna will be around 75 ohms in the flat configuration. A 300 ohm dipole would be a closed loop. Making it an inverted V would lower the impedance somewhat but a 75 ohm to 50 ohm mismatch is not that great.

Currently, I'm Contracting and living in an apartment. Of course there is no attachable antennas allowed. So I've been eying the buddy-pole concept but find it flawed right away.

This buddy-pole is directed towards bare-foot HF rigs, QRP, FD, etc. But being a flat Horizontal dipole the there will be a gross impedance coax mis-match (300 ohms to 50 ohms).

With just a lil more metal they could put the Hamstick elements at 120 degrees angle (inverted V) which has the reactance of 50 ohms. [I'm sure you see where I'm going with this.]

The super short Hamstick elements are already a significant compromise but then add this impedance mis-match and I'm not to eager to buy this dipole gizmo antenna compromise. BUT if I could get to the MFG'er and put a bug in their ear to make a same type mount for 120 degree element model ---> Well I'm up for a buy and try!

Any leads on where/who the MFG'er(s) are?

N6JSX/0

****
FYI, I bought and installed a "3/8-24 HD ANTENNA 180 DEGREE LIFT AND FOLD OVER MOUNT T203EZ" for my SUV screwdriver whip. It has been on my SUV less than 30 days and is already bleeding "rust" from the internal position spring or un-plated guts. The outside may be chromed or SS but not the guts.

There are various antenna setups that often get confused with other antennas.
there are mounts that use a pair of whips, like Ham sticks or other brands, as a dipole configuration. these can do fairly well at times.
I have seen a few different makes that have the mount, just don't recall which brands right now.
I could use my big magnet mount on my roof (metal) for HF, but with my dipole setup, don't need to.
I have a set of Iron Horse whips, similar to ham sticks, that did well mobile when I first used them. Sweden, Finland and Russia on 20 meter mobile in Sept 2002, and Washington to the Sacramento area on 40 mobile.
of course, band conditions can vary, and what works one time may not another when conditions are not as good.
But, one can take a pair of whips and use them as a shorter dipole and do fairly well at times. better than nothing.
One can also mount a whip on top of a metal railing or fence, or a metal roof or awning.
Many possible ways to do it...
YMMV

3657. Re: Noise -

Yahoo group: ham-antennas (2008)
Date: 2008-01-14 00:50:27 UTC
From: aml_stl
Topic: 3635 Message: 3657

Hi all (again) -

Thank you for the responses and suggestions...but I guess I'll leave you good folks alone as the problem doesn't appear to be the antenna...

As an update to what I've found over the last couple of days, the buzzing appears to be constant and worse on 80 as I said before.

Today, I had a friend watch the S Meter (buzz was 20+) and listen for any change in the intensity while I went to the basement and slowly cycled each circuit breaker. There was absolutely no change in the interference while tripping any breaker.

Next we each took portable AM radios and did a complete sweep of the house again, basement, attic and both yards, and up and down the alley for a "leaky" transformer. Nothing...a slight background buzzing but nothing out of the ordinary...

I went out and disconnected the strap from the ground rod at the base of the antenna thinking maybe something was getting into the cable through a dirty or rusty connection and then traveling into the house, but that made no difference either...

Interesting -- I went in and tuned the radio a bit, ignoring the buzz, and discovered the buzzing occurs at regular intervals on 40 and 80 meters -- 3.498 / 3.597 / 3.695 / 3.797 -- and 6.775 / 6.875 / 6.974 / and 7.078 on 40 etc. a 100 kc apart all over the dial. Now, I assume it's on the other bands also, just lower intensity to where it doesn't jump out at me. I've had dozens of HF radios here, they're all done it.

So anyway, thanks for all the replies and helpful suggestions, but it doesn't appear to be the antenna so I won't bore the group with further posts.

Not sure what group would be interested in this...? Anyone know?

I've got another call in for the electric companies "trouble shooter" and I will post again if this one comes up with something (4 others have not).

Thanks again!

AML

3659. Antenna Question

Yahoo group: ham-antennas (2008)
Date: 2008-01-14 03:21:28 UTC
From: Jim
Topic: 1215 Message: 3659

Hi all,

Can anyone explain how ineffective an antenna becomes as you begin to receive signals that are not perpendicular, but almost from the end?

Thanks,
Jim

3660. Re: [ham-antennas] Antenna Question

Yahoo group: ham-antennas (2008)

From: Stan Kozlowitz
Topic: 1215 Message: 3660

Yes, in terms of voltage. If you have a antenna that is supposed to be vertical and the normal received signal is also vertically polarized the voltage induced is let's say 1 microvolt.

Now if the antenna were leaning over at a 45 degree angle, the voltage induced would be only 0.7071 uV because the sine of 45 degrees is 0.7071.

If the antenna were horizontal, but the incoming e-field were vertically polarized, theoretically, you would get zero induced voltage because the sine of 0 degrees is 0.

Hope this helps.

Stan,

What a great piece of information, thank you very much.

I interpreted his message differently. I go the impression he was talking about the difference between shooting off the end of, say a dipole, as opposed to shooting off the middle.

From: N9WB
Topic: 3662 Message: 3662

This is interesting. You could tell any nosey parties that your olde antenna would not work with digital TV.

I remember when color TV first became popular in Indianapolis. I was a teen age and worked at an electronics store. The new antennas started arriving with For Color TV on the package.

We also got a kit to convert our olde stock to Color compatible. It involved a sticker to place over the original label that specified that it was compatible for Color TV.

And for those of you who are new to the electronic game, If your current antenna works good with analog TV, it should work fine with digital. I am sure a lot of places who will be selling boxes or new digital TVs will be telling customers that they need to buy a new antenna also.

3663. A (small) super!easy 40&80&160 loop with 30db F/B receive ratio on 160

Yahoo group: ham-antennas (2008)
Date: 2008-01-14 09:13:19 UTC
From: van lincoln
Topic: 3663 Message: 3663

Read this month's (February 2008) QST about putting
a loop over your tri-band beam for 40-80-160 that works
like gangbusters, and has a 30db F/B receive ratio
on 160 meters for deep nulls and ROTATES as well.

Page 37 The W6TC DX loop, by George Badger, has gotten
all the antenna people drooling....

Best idea I've seen for a LONG time!

Hi Jim,

That is correct. I am putting up a Carolina Windom and the ends will be pointing east & west. I wasn't sure how this would affect reception and transmission in those directions. I remeber reading somewhere that the Carolina Windom may be close to omnidirecitonal, but I can't be sure.

Thanks for any info,
Jim

Although I cannot remember how the model looked, my Windom performs more like a vertical.

Just an FYI...

It varies with antenna type. When you look at a G5RV at higher frequencies it isn't bad at all. A 1/2 wave dipole at resonant frequency is almost a null. You kind of need a modeling program to look at the antenna you are going to run.

My understanding is that the Carolina Windom has vertical polarization by design. Shouldn't that give me a somewhat omnidirectional pattern?

3668. Airport Control Towers And Polarization ?

Yahoo group: ham-antennas (2008)
Date: 2008-01-14 17:13:20 UTC
From: rmrrgs
Topic: 3668 Message: 3668

Hello,

Have a new handheld scanner; GRE 500 model.
Has a rubber duckie for its antenna, which is pretty typical for these kind of scanners, of course.

Tried listening to an airport Control Tower (118.5 MHz AM), about 5 miles from the house.

Here's what I found playing around.

When the unit is held normally, that is with the antenna vertical, the airport comms from the Tower were really poor.
Lots of static and noise.

But, much better when held horizontally.
a. Any idea why ?

I would have thought that their antennas would be polarized vertically to communicate with planes.

b. any idea how airport Control Tower antennas are likely polarized (if at all) ?

c. and this one really confuses me.

The best reception, by far, is if I point the antenna vertically, but DOWNWARD ! Big difference from vertically up.

Wouldn't vertically up, and vertically down be identical and symmetrically the same re polarization, reception, etc. ?

Thanks,
Bob

The carolina windom has current balun at the top and a decoupling balun at the end of the vertical portion. If I am not mistaken this removes almost completely any radiation from that section of the antenna so basically what you are dealing with is an off center fed dipole. If it is erected 1/2 wave above the ground then direction would be a valid concern but if it is lower then it would be an omni drectional type of antenna. Just my understanding of the theory.

Not true according to the Radio Works' description from their catalog:

"The CAROLINA WINDOM was the first antenna to take advantage of `VERTtm' (Vertically Enhanced Radiation Technique). `VERTtm' is a radiating feed line technique that produces a controlled, low angle vertical radiation pattern. The effect is absent from most ordinary antennas. Field tests, user reports and seven product reviews confirm that the CAROLINA WINDOM will give you a remarkable performance advantage...
The Real Secret
It's the Vertical Radiator. Combined with the Dedicated Matching it is responsible for the low-angle, vertical radiation pattern."

I am well aware of what the adds says BUT can you explain to me how a matching device that is used to keep rf off the outside of that piece of coax is going to radiate anything if it is working like it is supposed to??????? Then there is the line isolator to inhibit anything that the first device missed. If you can explain that to me then I will agree with you however I have seen too many matching devices such as the one decsribed here burn up because they were being used on a frequency that was lower than the antenna was designed for. In most case the high current point that is located 1/4 wave from the end of the antenna wire is trying to get passed the the matching device into the lower portion of the antena, in this case the coax. Not being able to do this, the matching device heats up and the permiabilty of the the the baluns cores change value ultimately breaking down altogether and cease to function. Then the antenna does not work at all until you either replace the balun or remove it altogether. Of this is only been my experience . Seems like the Radio works guy just threw that paragraph in on the bottom of the add though as a second thought or something. Anyway like I said last time these observations come from my 40 years of hands on type of experience with this stuff and probably doesn't amout to a hill of beans to anyone else but me. Have a nice day there Puck!

It has to do with capacity (inductive and capacitive reatance) of the coax that this length of coax displays to the transmitter. The antenna works with other lengths of coax but I think it works the best on all bands with the 70 feet or more length. It s easier to tune with a tuner and on some bands the SWR may actually be at a reasonable level to where you don't even have to use a tuner.

Why does the G5RV like to have at least 70 feet of coax to work correctly?
[snip]

Simple, the extra loss makes it easier to tune ! (maybe) But its probably supposed to be some sort of coaxial impedance transformer. I prefer to skip the coax and use balanced feedline all the way to the shack to help eliminate losses.

Your are making the assumption that the Carolina Windom has a current
balun at the top. That's not true according to Radio Works
explaination:

"The 'Dedicated Matching Unit' used to match the transmission line (coax feed line) to the antenna is a special design that enhances transmission line radiation. Part of the coaxial feedline serves not only as the transmission line (or feed line) but, simultaneously, serves as a vertical radiator. The wire portion of the antenna is the counterpoise for the vertical radiator. The result is an inverted-vertical antenna located high in the air and free of ground losses. It is a very efficient vertical antenna."

As you know an off center fed antenna like a windom is inherently unbalanced. I would assume the "matching unit" is a type of voltage balun so the currents remain unbalanced on that part of the unbalanced coax feedline which serves as the vertical radiator. Their "line isolator" at the bottom is the RF choke or current balun used to prevent radiation from the coax feed from the "line isolator" to the rig.

I don't have this antenna and can't verify the claims but the theory behind this type of antenna seems pretty logical to me.

Puck
I never said that it didn't get rave reviews all I said was the the vertical polarize signal was a bit suspect because of the two matching and isolating devices therefore I wouldn't worry too much about omni directional wave pattern a high antenna heights. At low levels on the lower bands MOST all the siginal will be going straight up in the air as opposed to out a low take off angle so orientation would not be an issue. I didn't try to start anything with you there buddy!!!! Can we still be friends!!!! hahahahahahah

For matching purposes, and has nothing to do with performance. In fact, the antenna doesn't perform as well as a dipole fed with ladder line. The G5RV has coaxial losses.

Not true according to the Radio Works' description from their catalog:

"The CAROLINA WINDOM was the first antenna to take advantage
of `VERTtm' (Vertically Enhanced Radiation Technique). `VERTtm' is a
radiating feed line technique that produces a controlled, low angle
vertical radiation pattern. The effect is absent from most ordinary
antennas. Field tests, user reports and seven product reviews confirm
that the CAROLINA WINDOM will give you a remarkable performance
advantage...
The Real Secret
It's the Vertical Radiator. Combined with the Dedicated Matching
it is responsible for the low-angle, vertical radiation pattern."

That's not the original Windom, that is someone's design to make an attempt to improve the design.

The antenna described now as a Windom antenna isn't really a Windom. The Windom was developed by Loren G Windom and described in QST September 1929.

Basically, the first one was a dipole fed at about 1/3 of its length. It was not coax-fed, but fed with a single line and tuned against ground. I use this antenna at my QTH in Michigan.

What we now call a Windom is a dipole fed at 1/3 the length with coax. You must use a balun. The balun is a often a 6:1 type, sometimes a 4:1. A Windom made for 80m will also work fine on 40,20 and 10. With a tuner it can work on 30/17 and 12.

I didn't think you were trying to start anything! I was just trying to explain why the Radio Works antenna just may work as they say it does. I didn't mention the "rave reviews", someone else did. I have used such an antenna at field day and it did indeed perform well for working west coast stations on 80 meters when installed at a relatively low height. Sure, we can be friends. Sometimes the written word can be taked much differently than a face to face conversation. I intended no offense to you nor did I assume any from your post. Keep the transmitter pumping out the radio waves and tickling whatever antenna you prefer.

Speaking of which, I guess I'm a bit old school and prefer a balanced antenna fed with open wire or ladder line feeders to a balanced tuner. The only coax in my shack is a short piece running from the rig to the tuner!

Topic: 1215 Message: 3688

Here...I found an article expaining how the Carolina Windom WOrks:

Some early versions of the Windom antenna used balanced twin lead in combination with a 4:1 balun. Those designs did not have balanced feed, but used balanced twin-lead feedline. Windoms fed with balanced line do not take advantage of the 'Vertically Enhanced Radiation Technique.'

Enhanced Vertical Radiation due to the inverted Vertical Radiator The CAROLINA WINDOM, on the other hand, takes advantage and improves on the off-center design. In the CAROLINA WINDOM, the current in each of the wire radiator sections is out of balance. Coaxial cable (which is not a balanced line) will radiate when the voltage and phase relationships are not properly balanced.

Special Matching Transformer The 'Dedicated Matching Unit' used to match the transmission line (coax feed line) to the antenna is a special design that enhances transmission line radiation. Part of the coaxial feedline serves not only as the transmission line (or feed line) but, simultaneously, serves as a vertical radiator. The wire portion of the antenna is the counterpoise for the vertical radiator. The result is an inverted-vertical antenna located high in the air and free of ground losses. It is a very efficient vertical antenna.

Flat-top, Inverted-V The combination of horizontal high angle radiation and vertical low angle radiation accounts for the excellent performance of the CAROLINA WINDOM both locally and long haul (DX).

Line Isolator The LINE ISOLATOR effectively separates the transmission line portion of the cable from the radiating portion. Vertical radiator length is predictable and repeatable.

THE SECRET A 'Line Isolator' is placed in series with the transmission line at a critical point. The Line Isolator provides a large inductive reactance at the insertion point (the action is similar to an RF choke). This effectively eliminates transmission line radiation beyond the point where it is inserted into the transmission line.

So, this is the secret of the CAROLINA WINDOM'S remarkable performance. It's the vertical radiator. It is not some sort of 'black magic' or 'hype' as some speculate, its performance is quite real and explainable.

Jim

Think less in terms of counterpoise and more along the lines of a radial system. And I do believe that more radials would help you tremendously.

Right directly off the end, the antenna presents very little
cross section and no currents are induced in the conductor that
actually reach the feedpoint. Theoretically, the attenuation of
signals is infinite. In practice, no antenna is perfectly
straight or perfectly horizontal or vertical and most signals are
off-axis a bit, so they are down anywhere from 10-30db.

On the lower bands, signals from under about 500 miles away
arrive at high enough angles that the pattern looks more like an
oval than a figure-eight.

It s easier to tune with a tuner and on some bands the SWR may actually be at a reasonable level to where you don't even have to use a tuner.
[snip]

I've never seen a G5RV yet that never required a tuner. I know that some makers advertise it as such, but everyone of them that I have seen required a tuner - even on 20 meters which is the design frequency for the G5RV !

I am well aware of what the adds says BUT can you explain to me how a matching device that is used to keep rf off the outside of that piece of coax is going to radiate anything if it is working like it is supposed to??????? [snip]

On the Carolina Windom, the only "matching device" is the balun at the feedpoint that transforms the approximate 200 - 300 ohms to 50 - 75 ohms, the 22' down from that is a choke balun that allows RF to flow on the coax shield only on the 22' section above it giving it some vertical radiation, but the choke stops the RF at that point keeping it off the rest of the coax that goes to the shack.

If you are worried about not hearing stations off the ends of the antenna, then mount it as an inverted V to allow a broader area of coverage. The inverted V will hear better off the ends than a flat top arrangement will and will also transmitoff the ends better too.

I get threads messed up, so I apologize if this is a repeat.

If you have to use a tuner on a G5RV (which everyone does), then it negates the purpose for using one. Simply switch to a dipole fed with ladder line and you'll have a better performer.

I will be using 14-gauge, copper-clad steel for the horizontal radiators. I am assuming the Matching unit to be a 4:1 balun and the Line Isolator to be 1:1 current-type balun. Assuming I'm correct, how critical are the specs of these?

From: Herbert Murray
Topic: 3704 Message: 3704

Does anyone in the group know anything about magnetrons? I planning to do some experiments in transmitting microwaves.

I would like to use standard magnetrons from a microwave oven and believe I can beam further if operated at the same frequency and with the outputs in phase. I have no idea on how to do this. Please advise

Cheers,
Bert

Yes, though at most normal heights, there will be a large high-
angle component on 80 and 160.

I think you will find the Magnetrons are Tuned for only ONE
Frequency. It has to do with the way the tube is made.
You would not be able to change that.

From: steve95446
Topic: 3707 Message: 3707

I wonder if anyone can answer this. The Carolina Windom CWS-80 is 66 feet long, but works on 80m, albeit at a lower efficiency by their own admission. Does anyone know how they do this? Is is just a standard 66 foot 40m-10m OCFD and your tuner "takes up the slack" and tunes out the higher SWR on 80m, or is the balun something special.

I am currently making a 66 foot OCFD with a 4:1 balun and wondered if it could be make to work on 80m.

Topic: 3704 Message: 3708

The magnetrons used in microwave ovens can be moved down to the ham band. There have been quite a few articles published on using these magnetrons in ATV transmitters.

Good frequency control can be achieved by using the magnetron as the VCO in a PLL.

It is not possible to make two of these operate "in phase" to get more power. The 1100 watts output when used with a 3M (10ft) dish will give you enough ERP to cause small birds to fall out of the sky at 400 Meters (1/4 Mile)...

Read part 97 carefully... there are restrictions on using high power on frequencies above 400 MHz.

Ladder line is fine if you use a manual tuner with balanced input terminals, but a lot of us have auto-tuners built into the rig that only accept coax. At some point you would have to convert the feedline from balanced to coax. I have been using as short a length of coax as possible to connect from the 30 foot twinlead section of my G5RV to my equipment (about 21 feet) and it works quite well on most bands. 70 feet of coax would definitely have more loss.

Some of these antenna manufacturers don't have a clue how their antennas work. It doesn't matter. All that matters is that there are enough gullible people to believe their ads. I'm with you. I don't see how it could provide vertically polarized radiation if you have a choke on it?

The ads, in my opinion, don't explain it either. Or else I'm missing something here. I know I won't be buying one of these antennas.

Stan AA4XO

QRP_1@... wrote:
I am well aware of what the adds says BUT can you explain to me how a matching device that is used to keep rf off the outside of that piece of coax is going to radiate anything if it is working like it is supposed to??????? [snip]

On the Carolina Windom, the only "matching device" is the balun at the feedpoint that transforms the approximate 200 - 300 ohms to 50 - 75 ohms, the 22' down from that is a choke balun that allows RF to flow on the coax shield only on the 22' section above it giving it some vertical radiation, but the choke stops the RF at that point keeping it off the rest of the coax that goes to the shack.

If you are worried about not hearing stations off the ends of the antenna, then mount it as an inverted V to allow a broader area of coverage. The inverted V will hear better off the ends than a flat top arrangement will and will also transmitoff the ends better too.

3712. BC Interference With SG-237 and 160 Loop

Yahoo group: ham-antennas (2008)
Date: 2008-01-16 00:09:16 UTC
From: wb4ydy2
Topic: 3712 Message: 3712

I have a problem with a new SGC 237 auto tuner and a 160 meter loop. The loop is 550 to 560 feet of #12 stranded and insulated wire fed with about 65 feet of 450 ohm ladder line to the SG-237 tuner. I am using the standard 9 feet of coax/control cable from the rig to the tuner. I have 5 ferrite chokes at the tuner end of the coax/control cable.

This setup is picking up very strong AM BC interference on 160 and 80 meters. It is extreme on 160 with BC signals at +20 to +60 db over S9! The +60 db signal is at 1950khz and is WSM radio (650khz) which is at least 12 miles from me. But several other stations are also coming through. When I switch to a 160 meter Inv. L the BC signals disappear.

The loop tunes up well on all bands above 80 meters. It has some trouble on the low end of 80, below 3,600khz. But it doesn't come close to a match on 160.

I ran this loop for several years with a manual Ten Tec 429 tuner without any problems. The only difference with the manual tuner setup was the ladder line came into the shack and there was about 15 more feet of it. The loop is the same.

After playing with the problem for several days, I am wondering if this combination of feedline length and antenna length is "too good" for the AM BC band and the signals are overloading the rig. Does that make sense? Before I start cutting the feedline or antenna wire I would appreciate ideas from the group.

Thanks and 73,

Pete, WB4YDY
Nolensville, TN

Ladder line is fine if you use a manual tuner with balanced input terminals, but a lot of us have auto-tuners built into the rig that only accept coax. At some point you would have to convert the feedline from balanced to coax. [snip]

Well, most manual tuners today with a balanced output only use a balun inside the tuner for that purpose, so you could try a very short coax between the radio and a 4:1 balun. It may not tune all bands with the rigs built in auto tuner, but it would tune some of them. I have a little Icom 703 that I use portable and it has a built in auto tuner and I came up with a unun and endfed wire combo that allows all band operation via the built in tuner. With a 23' wire it covers 10 thru 40 meters, and with a 50' wire you get 10 thru 80 meter coverage. One operator that built the unun told me he got 10 thru 160 meter coverage with either a 75' or 100' wire. Don't know how well it will work with the autotuners in other rigs, but the tuner in the 703 is a fairly wide range tuner and mine has tuned as high as a 12:1 swr with no problem. Icom states it will handle up to an 8:1 swr, but most folks say at least a 10:1.

Actually, this is an interesting question.

Buried radials or those laying on the ground.:

When making radials, I grab anything that will conduct, bury it and hook it up. From an electrical standpoint, whether it is insulated and whether it is non-insulated at the ends, makes little difference.

However I have seen that in areas where the soil is acidic copper deteriorates over the years. It is usually a very slow process. but if you are using insulated wire anyway, sealing the ends from moisture might preserve the life of the copper inside.

Above ground resonant radials:

If you are talking about resonant radials above ground, like on a roof mounted vertical, I would insulate the ends. When the roof is wet, open ends could change resonance and if the ends rubbed against a metal object, it can cause static.

Buried or on top of the ground....

I have had good success just cutting the lawn very close then installing #14 insulated house wiring on top of the ground. I staple them with U shaped staples about 6 " long made from 3/32 hard wire or coat hangers. After a month of growing you can't see the wire or gutter guard.
I have never had a problem with the wire getting caught in the lawn mower I even use Aluminum Gutter Guard in the same fashion captured to the ground stakes with 3" stainless fender washers with lots of Noalox around the legs of my Hy Tower
I have never caught the Gutter Guard in the mower it works for me really well.

You can see the Hy Tower installation at ka9zap.com

Hi Gary,
There is a product on the market that's available through most of the discount stores and hardware stores called "Liquid Wrench" that is a super penetrant. It comes in a 12oz Spray can with a little straw to get the liquid into tight places. Don't confuse this product with regular penetrating oil. I've used it numerous times to loosen rusted bolts that were frozen solid. You just spray it on the joint and let it do it's thing and try turning the sections. Depending on how far in the sections go you may need to try several applications.
Good Luck. 73 Larry/K9GSD

First, stay away from heat, cold, hammers, and plumbers wrenches. I usually do more damage with those than anything else. I found a product called Kroil a few years ago and it loosens more rusted and corroded parts than anything I've ever found. If you can't find it locally, you can order it from http://www.kanolabs.com/

3726. Grounding

Yahoo group: ham-antennas (2008)
Date: 2008-01-17 01:36:48 UTC
From: Jim
Topic: 3726 Message: 3726

After estimating what it would take to do ground radial system, I've decided to just drive 5 8' rods in and connect them with 2" copper ribbon.

My original plan was to drive 24 8' rods in, over a 78' x 42' area and connect them with 2" copper ribbon. The cost for that is over $1,000.00

The new plan is to drive 5 8' rods, 10' apart and connect them with 40' of copper ribbon. The cost for this is around $150.00.

I know everybody is thinking that a $1,000.00 investment is minimal compared to the damage that may be done in the event of a strike, but I just don't have that kind of cash at the moment.

Any hints or suggestions?

Thanks for your help,
Jim

Are you grounding for better signal or lightning?
It it is for a better signal you do not need to Drive rods into the ground.
But you do need to lay out Horizontal wires that are just a little longer than the lowest frequency you are going to use.... Just scratch them into the dirt or lay them on the grass and keep them down and the grass will grow over them... It would be good to have 8 or so going out in all directions.
Think of it as a Counter Pose and not a Ground....

Topic: 3726 Message: 3728

Hi Dean, and thanks for the advice.

My understanding is that a good RF ground can make a lousy protective ground, but a good protective ground will also make a good RF ground.

I think I will opt for the lightning ground. However, I was thinking of augmenting the aforementioned configuration with a counterpoise of sorts, in the form of a continuous length of #8 bare copper wire going all the way around the house, both ends terminated together at the common grounding point. That will be about 140' of extra wire near the surface of the ground, perhaps 1/4" to 1/2" deep.

Any thoughts?

Jim

Jim,

I certainly want to be the last person to push for not being safe but you have to look at two things: possibility and probability. Is it possible that you will be hit by lightning? Yes. Is it probable? Only you can answer that.

Insurance companies have been selling stuff for years based on possibility but then pricing it based on probability.

WELL SAID!!!

It's the reason I do NOT buy extended warranties...ever! If I added up the cost purchasing every extended warranty ever offered to me, I would have spent well over what the regular cost of reparing (or even replacing) any one or more of those items would be. Not to mention, none of those items has ever broken down. I am ahead of the "game".

With that said, I do plan on buying an iCOM IC7800 in the future and thought it might be a good idea to implement my own "insurance policy" of a nice, quick, harmless path to ground for that strike might would otherwise have my name on it. I'm just not sure that the expensive way to go "insures" me any more than the way-less-expensive way.

I am doing quite a bit of reading and am feeling a certain comfort level for the more conservative installation I spoke about earlier, but I will need to sample many more sources before I take the plunge.

Thanks Jim,

Jim

I have no doubt that brass is better material, but don't think you could probably hear any difference on the other end. If your slinkies are exposed to the weather, on the other hand, you'd need to paint the steel slinkies to avoid rust. The brass might tarnish dark, but probably not actually corrode. I'm playing best guess here, since I'm not a metallurgist.

3732. 3 element yagi over a metal (steel) roof

Yahoo group: ham-antennas (2008)
Date: 2008-01-17 10:19:24 UTC
From: aadu.adok
Topic: 3732 Message: 3732

hello,

I'm planning to put a TA33-JR (3 el tribander) on top of my roof. The roof is metal covered (some kind of steel). Roof height is 28ft. Is it sufficient if my antenna mast is 8ft long? The total height from ground would be 28+8=36ft? Is 8 feet from roof metal covering sufficient and will not interfere somehow?

thanks,

Aadu Adok,
Tallinn - Estonia

The best insurance is to disconnect the equipment from the mains and the antenna when not in use, particularly during severe weather. Don't forget the rotor cable. Either unplug the rotor control from any outlet strip or have a plug that can disconnect the rotor cable.

A radio sitting on a wooden table with no antenna, power, or ground connected to it is not likely to suffer lightning damage.

From: Dean L.
Topic: 3726 Message: 3734

OK. If you really want to make a Lightning grounding system this is
the way I built cell towers and grounded them.
At the tower we ran #2 Cu wire off each leg out to a 8 ft ground rod
6 ft from the tower base. The rods were tied together in a circle
and ALL connections were Welded and not clamped.
All grounding both inside and out was done with #2 Cu solid tined wire..
At the building or equipment room. A Hilo Ground was installed.
This was a #2 Cu wire with stand off insulators placed in a circle
around the ceiling of the room. This was tied at the corners and
about every 20 ft down and outside to a ring of #2 Cu wire buried
around the outside. This ring was grounded with welding at every
corner and in the middle. And it was tied over to the tower ground
ring with two runs of #2 Cu.
So we now have the equipment room in a box made of the copper wire.
The Rings were also tied to a large Cu plate about 1/2 in X 4 in and
30 inch long. This is the Single Point Ground everything was
grounded to this with home run wires up and over head. All the coax
was grounded to the tower at top and bottom and again just as it
entered the building to the Single Point Ground. The equipment
bays were insulated from the floor so if any lightning came into the
bay of equipment it would have to exit via the ground wire and not
via the floor.
Even the doors and air units were tied to the ground system.
All power and phone lines must be tied to the Single Point Ground so
that when and not If it is hit the lightning must go to the grounding
system.
I have been in the buildings when lightning hits the tower and I can
say it all works well.
Now a Counter Pose for better signal is not to be connected at the
out end together. Think of it as Part of the Antenna like a
Dipole ... Or reflector..
Hope this was not too long...

That all goes without saying. But if I'm on the radio and lightning strikes, it would be nice not to fry along with the equipment. Lightning can occur without any thunderstorm activity, so it's possible that I don't see it coming. There are no windows, so I have to be extra "beefy" with the safety measures.

Topic: 3726 Message: 3736

Now that's a nice ground system. For my puposes, would you say #4 is suitable? Also, how often do you have to replace which elements of the system?

That should do it.... But it is never big enough... hi hi..
You should not ever have to replace anything if you WELD all
connections.
Most like to Cadweld but that is expensive... You can use a brazing
torch and brass rods to do about the same thing... But clamps are
only good for about a year then they get corrosion and have
resistance ...

3739. Whatever happened to trap dipoles??

Yahoo group: ham-antennas (2008)
Date: 2008-01-17 20:03:29 UTC
From: lecontejoe
Topic: 3739 Message: 3739

Back in the day -- back when AM was king, when men were men, when giants bestrode the Earth -- one could find trap dipoles everywhere -- B&W, AlphaDelta, everywhere. The concept was simple -- wire dipole with traps spaced out along the wire legs of the antenna; traps tuned for 10, 15, 20, and 40 meters; dipole fed with coax. On 80, the entire antenna was in use and the traps electrically shortened the dipole as you went up the bands. Result was a dipole that was shorter than the 135 feet required if fed with balanced line.

I have a small one that I built covering 40, 20, and 15 -- purchased 20 meter traps from AlphaDelta. The dipole is 28 feet per side -- a standard 40 meter dipole should be around 32-33 feet per side -- the trap effectively shortens the antenna. On 40, it works as a half-wave dipole; ditto for 20; on 15 it works as something like a 3 wavelength dipole. Mine is up around 25 feet;
-- fed with RG-8;
-- coax is rolled into an 8-inch diameter coil at the antenna, 5 turns, makes a choke;
-- SWR on 40 is under 2:1 for the entire band;
-- lower 100 KHz of 20 is high, 3 or 4:1, rest of band is under 2:1;
-- 15 is tricky, lower 200 KHz is under 2:1, rest of the band is, well, take your chances.

Now, instead of trap dipoles, all I find are terminating resistors masquerading as "shortened dipoles."

I lost a lot of stuff in Hurricane Katrina and am looking for a set of traps to build a coax-fed dipole for 10-15-20-40-80. Anyone manufacturing this stuff any longer??

Thanks.

If you are grounding for lightning protection...forget it. I've never met a ham whose station took a direct hit that did not suffer significant damage, regardless of the ground system used. One of these hams had invested over $3000 to install a broadcast station quality ground sytems, including bonded steel mesh blanketing a 50 x 50' area beneath his tower. His station was disconnected, but the strike blew up his single point grounding box and melted a big patch of vinyl siding.

My advice: Do what you can to minimize the effect of a direct hit, unplug your station from the antenna system, lay down a decent station ground w/ the expectation that there will be something damaged if you take a direct hit.

Wait a minute while I don Kevlar...awaiting barrage from naysayers.

Why don't you roll your own traps? A Google search for "antenna trap design" will yield a bunch of how to.

Only a fool would spend $10,000 on a rig and not provide for the best possible lightning protection that he/she could for the equipment, his/her family and him/herself...only a fool.

That is just bad advice, sir. If I was open to that line of thinking, I would have never asked the question.

Only a fool would spend $10,000 on a rig and not provide for the best possible lightning protection that he/she could for the equipment, his/her family and him/herself...only a fool. [snip]

In my opinion, only a fool would spend $10,000 on a radio in the first place ! But I agree that nothing will protect the equipment from a direct lightening strike - no matter how good the ground system is. And I don't believe that lightening only strikes the tallest object around either. I've seen lightening strike trees that was much lower than anything else around them including my antennas. Lightening once knocked a limb out of a big water maple in my yard. The limb was about 1 foot in diameter and only about 10 feet up the tree. My antenna was 30 feet away and 40 feet in the air and the lightening never touched it.

I think the best was to prevent strikes though and so far I haven't had any strikes here while using it, is to keep the feedlines grounded when not in use. This keeps charges from building up on the antennas and feedlines that can trigger a strike. To ground the feedlines though, don't depend on switches. Actually disconnect the feedlines from the equipment and connect them to a good solid ground. I do this with a ground box that I built. Its a cast aluminum box with coax connectors mounted on it for each feedline I have and each center pin is grounded to the box with a heavy copper strap inside the box and the box is bonded to the ground strap for the shack. When not in use, the feedlines are disconnected from the equipment and connected to the ground box. My ground is 3 8' copper clad rods driven into the ground outside the shack and all bonded together with heavy copper strap and also bonded to my electrical service ground. Only problems I've ever had was when lightening struck the phone line somewhere in the neighborhood. It destroyed 2 phones and the modem in a computer. I now disconnect the modem lines and phones during a storm except for one cheap cordless phone that only cost about 10 bucks at a flea market so there will still be one on incase the family needs to get in touch during emergencies.

But no matter what you do, lightening can still do damage. I've seen it hit the power lines and blow the meter base of the side of a house, and it blew some of the outlets out of the wall boxes ! Kind of hard to disconnect from the power company whenever you want !

And it is not just the cost of replacing the ham station when you take a direct hit. You have to think about adding enough protection for your structure.

I took a direct hit in May of 1999 after just putting up a small 35' Rohn 25G tower along side my house in October of 1998. BTW, this is no longer a recommended practice of putting your tower up along side your house now per our local ordinance, but that's another story.

I was in a rush to finish things off with the installation in October, and I just threw a couple of 8 foot ground rods in the ground 8 feet out from the tower and said that's good enough. I only had 12' of mast with a triband, a VHF and UHF beam and a dual band vertical on top. Well... in addition to the strike taking out my entire ham shack, I had another $14K of damage to the house, and was at risk for a short time just after the strike for a fire to occur in one of the inside walls of our home. The high voltage surge also took out computers and TV's in five houses in our neighborhood, and fried several under ground cable TV runs to several of my neighbors homes. The distribution box for the neighborhood happens to be in my back yard. My point here is that direct strike may not only effect your property, and certain care should be taken to do the very best you can to avoid major damage, not only to your propery but others as well.

It does not require thousands of dollars to insatll a decent workable ground ssytem. It would be nice if we could afford the ground systems out lined in Polyphaser's grounding manual, but that is not practical. However, we sure can use some of that system at much less the cost.

Iv'e taken the threat of lightning much more serious since my dirct hit 9 yeras ago. I have installed 12, 8 foot ground rods on my small 50'X 140' lot per Polyphaser recommendations, connected with #4 stranded copper wire.(should really be heavier gauge than that) All of my feed lines are connected to Alpha Delta lightning arrestors at the base of the tower and the whole system is tied to a single point ground system.

My biggest expense were the Alpha Delta arrestors, as I needed 10, for the 10 feed lines coming into the shack. ALL equipment in the shack is grounded to the single point system using 3" wide copper foil.
All feed lines entering the shack are fed into Alpha Delta switch boxes which are mounted on a copper wall panel, for a common ground point in the shack. During a threat of storms, they all get switched to center common position.

I know the probability exists that I will be hit again sometime in the future, and the best I can do is put in the best system I can that will divert as much energy away from the equipment and house as possible.

I believe, only a fool would think he is invincable to the power and destruction of a lightning strike!

BTW, the root cause of my strike was poor judgement on my part when installing the VHF/UHF vertical at the top of the mast. I added a short 5 foot section of 1" radio shack mast to the main 1 1/2 galvanized mast, in order to get enough vertical spacing between the 432 beam and the vertical. I totally had a brain fart about attaching two different metals together.

Alpha Delta does make their iso traps but they don't list them on the
web site as being separately available. You could try calling them to
see if they sell them separate.

Towers attached directly to the side of a house are a no-no in many jurisdictions specifically because of lightning. As a fast rise-time pulse, lightning cares less about resistance, and more about inductance. So, it can hit the top of your tower, then leap from tower to an AC power line inside one of your walls and do damage. If that path is physically shorter than travelling the rest of the way down the tower to your ground rods, then the ground rods are not going to save you from much.

I saw just such a lightning hit in Norcross, Georgia. It was a commercial tower installation, bolted to the side of a two-story commercial brick building...where we were developing satellite TV equipment as used by cable companies. The attachment point was the flat roof, which extended some 4-5 feet away from the building. This was a sturdy tower, three feet across at the base, and it had all the PE, structural engineering, code inspector approvals you could think of. The lightning grounding system included several dozen rods and 00 copper wire. It is hard to imagine anything sturdier in terms of grounding. Yet, the lightning path was etched on the back of my eyeball - I saw the strike hit and leap five feet across to the brick building, fully 25 feet off the ground. The lightning bolt inside the building leapt from an outlet box (two feet from where the lightning struck outside) approximately fifteen to a metal support pole that held the roof up. One of our engineering techs was sitting at the bench, no more than five feet from the path of the bolt. Scared to death, but uninjured. The burn marks were about a foot in diameter.

The "rule of thumb" is that the tallest object is most likely to be hit, but you are supposed to keep an area around it completely clear up to a distance equal to the height. In other words, a 50 foot tall tower should have no valuable structures within 50 feet of the base.

In addition to the lightning risk, fascia boards on houses have no ability to support a load, so if you have not improved the structure under a fascia board, it's a terrible thing to bolt a tower to.

I've been lucky - I've never bothered with a grounding system. But I never had a tall enough structure to be a risk when I lived in "lightning territory". My first 50-footer was a mast, clamped to the back of my house, on an insulated base so I could base-feet it on 160 meters, and guyed with rope. But - it was in a part of the country that had not seen a lightning strike in about ten years. And, I figured, if one happened, it was probably the high voltage lines about 150 feet south of me and on 150 foot towers that were at risk.

I'm now in an area that gets lightning occasionally, but nowhere near like east of the Mississippi...and my 50 foot tower is going to be 250 feet from the house.

My sympathy, Gene. That's gotta be a tough situation. I'm glad to hear that no one got hurt, at least, you didn't mention anyone.

Anyway, my setup will leave the antenna that I want to put up in the open, more venerable to strikes than a lot of folks. I'm just not bypassing any chance I have to save equipment, my house and especially people.

Thanks for the support,
Jim

How is "attaching two different metals together" associated somehow
with a lightning hit? Is this supposed to attract lightning?

Dave W8NF

It would create a voltage drop (resistance), due to the corrosive action between the metals. In other words, the grounding of the upper part of the mast was defeated...I guess.

From: Gene Gabry
Topic: 3744 Message: 3754

Dave,

Your lightning strike experience had many similarities to my strike. My dual band vertical was the initial attack point at barely 60' above ground to the top. The radiator and most of the mount were vaporized. I had lots of fiber glass shavings all over the back yard! As the charge traveled down the tower, streamers jumped off at the gutter. There were multiple arc burn marks across the two legs of the tower across to the gutter. Both 20 foot sections of down spout on either side of the back of the house were blown apart from the main gutter system and were basically nothing but pieces of shrapnel in the back yard smoldering. I believe it was one of the streamers from the down spout around the corner where my underground electric service enters my basement, jumped and punched a 2 inch diameter hole in the siding and through the wall board where the electric panel is mounted. Not only did it melt every circuit breaker in the panel, it fused the buss bar to the back side of the panel and knocked the panel off the studs and concrete wall. This streamer was not yet done. There is an outlet directly across from the electric panel where the streamer continued on through to the other side which was my ham shack. The wall around the outlet where this streamer entered was blackened and burning hot to touch minutes after the strike. The fire department monitored this area for a while before we were cleared to re-enter the house.
This next part is very interesting. The surge that entered my shack through the outlet, followed a path through the surge protectors to my computer, radio power supply and 3 of 4 rigs. The only 2 pieces of equipment that were not damaged was one HF rig, which was the only rig connected to a grounded switch box, and, believe it or not, a cordless phone that was plugged into the other plug of the same outlet where the surge entered. The phone was not in the AC surge protector chain! The surge protector was in little bits and pieces all over the shack, with some pieces in bedded in the dry wall. This streamer then followed this AC line up into the kitchen above and fried all of the GFI outlets on the first floor, taking out the range lites and one ceiling fan before exiting. Now

for a real interesting part of this story. I did not have to call the fire department as a neighbor of ours three doors down and across the street did. At the same time I got hit, her ceiling fan started arcing and sparking and spinning with no electric applied. At the same time I was hit a bolt came out of her ceiling fan, into the carpeting, starting a small fire in her family room!

As for my tower position and mounting. I really didn't have much of a choice in this location. The electric service runs underground diagonal through by back yard, and I have a pretty deep and wide swale in the middle of the back yard that runs the entire width. That is where I would have liked to have put the tower, but that would have put it way too close to the underground eclectic service and that area ends up like a river when it rains as it is part of water run off to the sewer main, which happens to straddle my property and the neighbors!
Although I didn't really need to house bracket the tower, as I went way over kill on the concrete base, I felt more comfortable climbing (psychological) with two brackets anchored with 4, 4 inch lag bolts into the ends of two rafters.

As my XYL and I reminisce about that episode from time to time, we can now make some humor of it. At the time of the strike, my wife and I and our three boys were watching a movie on TV, waiting for our pizza to be delivered. Two of our boys were walking through the kitchen on the way back into the family room when I turned to look at the wall clock in the kitchen to see if our pizza was late. At that instant is when we got hit. It was like slow motion. I felt the floor underneath my body drop away, my two boys leaped into the air diving into the center of the family room where my wife and were sitting on the floor. And I will never forget the intense bright white light and instantaneously bomb like sound and force, then everything went dark. All five of us stayed huddled together on the floor, shaking for several minutes. One of my sons finally asked with a nervous voice "are you still alive"!
Not something I want to ever repeat!

Anyway, that's my story and I'm sticken with it!

My method of attaching one mast to the other was via
two u-clamps with there being a compression contact
between the two different metals. The metals had
oxidized causing a high resistance between the two.
Basically the top 5 foot section with the vertical was
now at a different potential then the rest of the
system, and became the weak point. It is highly likely
that the first streamer originated from this point.

3756. Grounding

Yahoo group: ham-antennas (2008)
Date: 2008-01-18 18:34:49 UTC
From: Brian Hall
Topic: 3726 Message: 3756

My point was eloquently illustrated...A previous poster described in detail how a commercial tower site is ground and it is clearly unreasonably expensive for all but a very small minority of hams.

Another poster described the damage a lightning strike can cause (would be interested to know if his shack was disconnected).

A high quality ground is designed to prevent a strike (like a lightning rod does), but dissipate energy in the event one occurs anyway.

My point was simply this: Install as good a ground system as you can afford using good engineering practices...but expect that it will not fully protect you from a direct hit. At a minimum, use a single point ground EXTERIOR TO THE HOUSE, and DISCONNECT YOUR ANTENNA SYSTEM (and preferably connect it to you ground when not in use).

This is not "fool's" advice, merely a dose of reality...to me, a fool is anyone who spends $10,000 on a rig in the first place. That being said, anyone who does spend that on a rig should be able to afford a decent station grounding system.

From: gadzooks.mike
Topic: 3725 Message: 3757

You guys are going to make me work here. Now I have to climb up into the attic and see what mine is made of - brass or steel. (Curious? Me? Yup!)

I bought them at Cracker Barrel and strung them in the attic as a dipole. As a listening antenna, it works great. Haven't tried to transmit using it, but wouldn't be surprised if it works just fine.

Good luck!

From: Jim
Topic: 3726 Message: 3758

Your reality is not necessarily "THE" reality.

If you had done any reading, you would know that there are many installations where people watch direct hits regularly, with absolutely ZERO damage - it's juat another part of the day. This is not as difficult to achieve as one (you) might think, given enough time to educate yourself.

As for the $10,000, it's all relative. Your salary might reduce that limit considerably. Mine allows it quite comfortably. I'm not sorry about that. Some folks get their kicks with expensive cars. Others, like me, expensive radios. Still others don't put much value in the finer things, so, to each his own.

This conversation is not about what I decide to spend on my equipment. My decision to tell you was not to solicit negative feedback from you about it, whether it's jealousy or otherwise. I am merely tring to construct the safest possible station that I can and if you would rather sit there and turn my words against me, I'm all ears. If, on the other hand, you have more positive reinforcement to contribute, instead of the mild negativity I sense, I'm all ears.

I will have my expensive rig longer than you will have negative comments about it.

Later, dude.

I will have my expensive rig longer than you will have negative
comments about it. [snip]

Jim,
First let me apologize for making the statement that "only a fool
would spend $10,000 on a radio" as I did not intend it to be an insult in
any way - sorry OM. What I was basically saying was that even if I could
afford a rig at that price, I would not spend that much for one - same
with cars because I'm more of a utilitarian type of person and not into
fancy things. I'm very glad to hear that some folks can afford them
compfortably, its just the ones that can't and still do and put their
families in a financial bind that bothers me. And I agree that cost is
relative to ones income level. I'm not wealthy by a long shot and not
poor either, but I've always been easy to satisfy with the simple things
in life - small simple radios, hombrew simple wire antennas, economy
cars, whatever as long asthey do well for me and I'm happy as can be with
them. My main rig here is a Yaesu FT-840 - a very simple rig and I do
not use all the features it has ! I also have an Icom 706MkII, an Icom
703, two Yaesu FT-747GX's, a Yaesu FT-7, and several monoband QRP rigs,
so as you can see, quanity is more important to me than quality - my xyl
says I have too many, and I keep telling her that the only thing a man
can have too much of is women ! ;^) But any, I hope you'll forgive me
for that foolish statement of mine - after I read it, it looked insulting
to me too !

Topic: 3726 Message: 3765

Sorry But I don't Buy it...Nor do I believe it...The best way to assure lightning protection Is to unhook everything. antennas, power supply, rotar cables, ect, ect.... I once had a computer that was unplugged from the power and the modem connection also unplugged and the computer was off....A lightning strike just outside the room were the computer was at, totally unhooked from everything and off. Well When I hooked it all back up after the storm and turned it on...Well the Video card was toasted....The lightning strike and high static discharge that came with it fried the video card....I now have things located so they are not near and outside wall. They are only near inside walls...Will it make a difference...I don't know but I luckily have never had that problem again...So far.....The same goes with the radio equipment. Even if its all unhooked there is still the possibility from a near strike that you equipment could be damaged....If I had a $ 10,000 radio (Thats
never gonna happen to me, But I am glad for you) I would unhook it and put it in the closet or a lead box whenever lightning was near....I would rather be over protective than risk losing my rig ... I just don't have the money to replace the equipment. No matter a $100.00 radio or a $ 10,000 radio....Better safe than sorry....I can't even imagin have'in your kind of money. I always wondered what it would be like to not have any money problems... Man that would be sweet....
Well at least I have my Common sense. To each his own I always say....
If you have any other money you would like to throw away let me know, I could sure use it...Second thought, You better keep it because you are gonna need it if you keep your Equipment hooked up and have a Near lightning strike...I hope you have some fire extinguisher's handy....Good Luck to you...I hope that you will not be operating your rig with a metal mike during a lightning storm.....
Some things you just can't buy with money I reckon....You ever heard of Ben Franklin.....Hmmmmm

All donations may be sent to " Bill In Ohio ".....73's and once again because I think that your gonna need it....GOOD LUCK.....You've Been Warned.....

First time I saw one of those $10,000 radios advertised I thought to myself, Who in the heck can afford something like that ...Now I know....I guess we do learn something every day....Thanks.....

Jim <jimemack2000@...> wrote: By the way, if your ground system is designed properly, not only can
you leave your equipment connected, but it's probably safer to do
so. I 've been reading the most up-to-date publications and they all
say that one of the worst things to do is disconnect the antenna
system - it's actually more dangerous to do so.

Dude, you need a lot of training.

Lightning isn't the evil you think it is. It's only the opponent you have'nt defeated.

Let me ask you one question...when was the last time you heard a radio station announcer say "I'm sorry, ladies and gentlemen, but we must get off the air immediately and disconnect all of our antenna systems until this thunderstorm passes. By the way, we are also forced to turn off everything at the station, including the computer equipment, lights and the servalence cameras...our sincere apologies for any inconvenience this may cause."?

By the way, Although $10,000 is not the burden it used to be in my life, it is still a lot of money to me. And, if I had an extra $10,000, you would probably be the first person I would buy the radio for...

...but you would have to replace the video card yourself.

3769. antenna corrosion

Yahoo group: ham-antennas (2008)
Date: 2008-01-19 05:10:20 UTC
From: Dave
Topic: 3769 Message: 3769

I have been given a couple of older 20 meter antennas,(HyGain 204BA), that are pretty well gunked up withn corrosion, especially the element to boom clamps. Normal stuff for their age, but, I'd like to clean them up before I reassemble them.

Anyone have any ideas, other than good ol' fasioned elbow grease, on how I could clean these things? I have seen some stuff on television called "BAM" that lokes like it might be the answer, but I don't want to destroy the clamps in the process either. And then once cleaned any ideas on how to keep the corossion away (within reason I mean). I've heard that spraying Krylon at least retards oxidation of the aluminum.

Thanks in advance for your help and advice.

As stated before on this thread I believe...Most Amateur Radio operators Don't have that kinda of money (Resources) to spend like the Big Business folks.....And even when The big busuness folks spend all that money it is still no guarantee...I never said lightning was Evil....But it is one of the most powerful forces of nature, Is it not....

I'd love to build a large capacitor and be able to store the energy of that lightning....The power companies would not want to see something like that though, would they....

Oh and one other Fact
you said
" Let me ask you one question...when was the last time you heard a radio station announcer say "I'm sorry, ladies and gentlemen, but we must get off the air immediately and disconnect all of our antenna systems until this thunderstorm passes. By the way, we are also forced to turn off everything at the station, including the computer equipment, lights and the servalence cameras...our sincere apologies for any inconvenience this may cause."? "

Funny you should say that. as a matter of Fact one of our local TV stations here in Dayton, Ohio (WHIO TV) has been Blasted off the air several times over the years. This just happened not too long ago. And yes it does take them some time to get back on the air. Feel free to verify my story. WHIO TV has a very large tower and it gets hit all the time...No they don't go off the air on every lightning hit but enough to cut into their profits with the repair costs.....Which us regular folks just can't afford. So it easier and cheaper and smarter to just unhook everything....Of course the Big Business TV station and radio stations cannot go off the air and unhook everything when lightning is approaching...Thats just Silly that you even said that...A lightning strike on them is just the Cost of business and providing a service...Come on now.....Channel 45 or fox 45 has also been knocked off the air by lightning quite a few times also, as have the police and fire systems
and other systems of this type. I once dispatched for a company years ago and lightning took out our repeater once also...Its their cost for doing business...For you to say that no broadcast systems are ever knocked off the air by lightning is just plain uneducated about the matter.....
Once again...Good luck....

Bill In Ohio

Jim <jimemack2000@...> wrote: Dude, you need a lot of training.

Lightning isn't the evil you think it is. It's only the opponent you have'nt defeated.

Let me ask you one question...when was the last time you heard a radio station announcer say "I'm sorry, ladies and gentlemen, but we must get off the air immediately and disconnect all of our antenna

systems until this thunderstorm passes. By the way, we are also forced to turn off everything at the station, including the computer equipment, lights and the servalence cameras...our sincere apologies for any inconvenience this may cause."?

> Sorry But I don't Buy it...Nor do I believe it...The best way to assure lightning protection Is to unhook everything. antennas, power supply, rotar cables, ect, ect.... I once had a computer that was unplugged from the power and the modem connection also unplugged and the computer was off....A lightning strike just outside the room were the computer was at, totally unhooked from everything and off. Well When I hooked it all back up after the storm and turned it on...Well the Video card was toasted....The lightning strike and high static discharge that came with it fried the video card....I now have things located so they are not near and outside wall. They are only near inside walls...Will it make a difference...I don't know but I luckily have never had that problem again...So far.....The same goes with the radio equipment. Even if its all unhooked there is still the possibility from a near strike that you equipment could be damaged....If I had a $ 10,000 radio (Thats
> never gonna happen to me, But I am glad for you) I would unhook it and put it in the closet or a lead box whenever lightning was near....I would rather be over protective than risk losing my rig ... I just don't have the money to replace the equipment. No matter a $100.00 radio or a $ 10,000 radio....Better safe than sorry....I can't even imagin have'in your kind of money. I always wondered what it would be like to not have any money problems... Man that would be sweet....

Thanks Jim,
I just believe that unhooking things is the best way to protect yourself...Why take the chance....Yea it can be a pain. But its a pain that usually doesn't cost me anything....And thats a good thing....I'm one of those guys that bad luck is always around...I gotta watch my @ss.....LOL
73's
Bill In Ohio....kc8ilp

Oh and my main HF Antenna is a 229 foot End fed radom long wire raped all around the place here, highest point abt 70 feet of so... When I hear lightning in the forecast you can bet your....You know what, that I am gonna be unhooking it and throwing the wire out in the yard....Talk about a lightning rod...Boy....LOL

Jim <jimemack2000@...> wrote: By the way, Although $10,000 is not the burden it used to be in my

Hey...I've been thinking (UT O) I've had my eye on a sweet Software defined radio, Computer included.
You get me that and you will save a few bucks and then I could replace the Video Card.....Hi Hi.....
Heck, just get it without the video card and I will just add it myself.....

Bill In Ohio
Holding my breath and waiting....

I'm so Happy I gotta sit on my hands just to keep myself from waving at everybody.....Thanks JIM.....

Be careful and good luck

Jim <jimemack2000@...> wrote: By the way, Although $10,000 is not the burden it used to be in my
life, it is still a lot of money to me. And, if I had an extra
$10,000, you would probably be the first person I would buy the radio
for...

...but you would have to replace the video card yourself.

Jim

Jim makes a very good and valid point here. The reason we amateur operators have the need to disconnect our station is because it probably is not grounded properly, to the standards required to disapate the strike completely away from not only our stations, but also our home. In a properly grounded environment, there is absolutely no reason to not only not disconnect the station, but you should be able to continue operating as well. Lets face it, we are AMATEUR operators, from all walks of life, not all engineers.

Now, my next statements are not meant to to critisize anyone, but to just be as factual and honest as I can, There will be some in the amateur community that have no idea about proper grounding, and some come here for advise. We should be elmers and mentors for them and help. There will be some in the community that believe a couple of ground rods next to their instalation is a sufficient ground. Then there are those who believe that it does not matter to be grounded at all because whether I'm grounded or not, I'm going to get hit and my equipment is going to get destroyed anyway so why bother.
Even those amateurs who do every thing correct, and by the book, do encounter some damage, mostly due to a weak link in the system. One corroded connection at a critical point in the system makes the whole system vunerable. That's why some commercial systems fail as well. It just happens.
I think we all should help one another here to achieve the best and safest sysytem we can put together without all the badgering, and insults.

Station grounding is a critical antenna topic that can be better served by teaching and instruction, not badgering and insulting.

Jim makes a very good and valid point here. The reason we amateur operators have the need to disconnect our station is because it probably is not grounded properly, to the standards required to disapate the strike completely away from not only our stations, but also our home. In a properly grounded environment, there is absolutely no reason to not only not disconnect the station, but you should be able to continue operating as well. [snip]

I may not have the "perfect" station ground, but I purposely put my tower out away from the house (25') away and have each leg of the tower connected to its own 8' ground rod with all 3 rods bonded together. All feedlines come down the tower to ground level where they are also (shield side) grounded then taken over to another leg of the tower for a double bend at ground level, then back up the tower to about 10' and then over to the house. My reasoning for this is because lightening will almost always take the straightest path to ground and with my tower grounded and feedlines grounded before they come to the shack, I figure any strike will be disapated before it gets to the shack. Do I think I would not suffer any damage in the event of a direct hit - NO ! And I do not choose to operate during a storm just because I don't like being in contact with the equipment during a storm and the bands are so noisy during a storm anyway, I just do something else until its over. I would rather be safe than operate no matter how good the station is grounded. But I do feel that having a good ground will help eliminate strikes since it keeps charges from building up that triggers a strike. I also believe that strikes are much more likely to come in on either the phone or power lines simply because there are much more conducting material around to be struck in the first place.

Lets all keep it safe !

The best grounding situations still get hit with lightening. I have witnessed it.

And... amateur radio ops can be and often are, the best engineers in the world.

Just live next to a tower.

"lightening will almost
always take the straightest path to ground"

Not correct. Lightning will take the path of LEAST resistance.

I would then say to you that it wasn't the best grounding situation.

The article sent out earlier is written by an expert. I've read it before and it is excellent. He is a ham and he is an expert.

1. Don't be in the ham shack during a close lightening storm (at least 10 miles). Even with a very good system, you are not going to deflect 100% of the electrical energy... More like only up to 80%. That means 20% of a million volts is potentially headed toward your radio (and maybe you).

2. Commercial stations stay on the air because they operate remotely.

3. Have a radial system with several ground rods (read the article).

4. Be safe and smart. Lightening will jump, it can couple and it will be unpredictable, that I can predict accurately. To try and outsmart lightening is ignorance. "It ain't gonna happen."

Safety first and read the article before drawing any of your own conclusions.

"lightening will almost
always take the straightest path to ground"

Not correct. Lightning will take the path of LEAST resistance. [snip]

Well, the shortest point between 2 points is a straight line and the shortest path will also be the point of least resistance. That is if all the connections are good and solid. So by providing a short, straight, low resistance path to ground, you can dissipate the strike before it gets to the shack.

And even though you have 4 or more ground rods, you will not know if any of them are truly ground (zero to 2 ohms) until you use one of those meters designed to measure the ground resistance. It can't be done at DC, so you can't take a Fluke VOM and measure it. The meters designed for this cost about $1500, so unless you have a LOT of money to waste, go borrow one from the phone company, or a cell-phone company.

One of the local hams gave a talk at the Richmond Amateur Radio Club last year. And he showed us several situations where people thought they were grounded, but the resistance was over 2000 ohms. In his own situation, he had two ground rods driven two feet apart. One had less than 2 ohms resistance and the other was over 2000 ohms.

Bottom line is: just because it looks good, it doesn't mean it is. YOU HAVE TO MEASURE !

Good luck on all your grounding.

Stan AA5XO

QRP_1@... wrote:
Jim makes a very good and valid point here. The reason
we amateur operators have the need to disconnect our
station is because it probably is not grounded
properly, to the standards required to disapate the
strike completely away from not only our stations, but
also our home. In a properly grounded environment,
there is absolutely no reason to not only not
disconnect the station, but you should be able to
continue operating as well. [snip]

I may not have the "perfect" station ground, but I purposely put my tower
out away from the house (25') away and have each leg of the tower
connected to its own 8' ground rod with all 3 rods bonded together. All
feedlines come down the tower to ground level where they are also (shield
side) grounded then taken over to another leg of the tower for a double
bend at ground level, then back up the tower to about 10' and then over
to the house. My reasoning for this is because lightening will almost
always take the straightest path to ground and with my tower grounded and
feedlines grounded before they come to the shack, I figure any strike
will be disapated before it gets to the shack. Do I think I would not
suffer any damage in the event of a direct hit - NO ! And I do not
choose to operate during a storm just because I don't like being in
contact with the equipment during a storm and the bands are so noisy
during a storm anyway, I just do something else until its over. I would
rather be safe than operate no matter how good the station is grounded.
But I do feel that having a good ground will help eliminate strikes since
it keeps charges from building up that triggers a strike. I also believe
that strikes are much more likely to come in on either the phone or power

lines simply because there are much more conducting material around to be struck in the first place.

Lets all keep it safe !

Hello gentlemen: Not trying to debate this theory, just had to toss
in a thought provoking comment - A friend of mine had a 95" tower,
guyed, and fully extended with a 6 element triband beam a top of it.
Lightning as close as we could determine, came down around and
underneath the triband, between the 3 way guying system, and struck
a small redbud tree that was 12 foot from the base of the tower, blowing
it completely out of the ground, leaving a washtub sized hole, and there
was no damage to any part of the radio gear which was hooked up at the
time. Yeah mysterious ways!
Another one - There are 4 houses connected to this large pole mounted
transformer in the rear of my home. Lightning came down the hi tension
line, (now I am an amateur operator with loads of copper in the ground
and all grounds bonded together as good as I am capable of making),
Which house do you think had the most damage? Yessir - the one with
the path of least resistance. Very little damage to all houses, light bulbs
primarily. Not at my house where I have the good grounds - I was the
magnet. So now I am wondering - Maybe I should take my vast wealth
of radio knowledge and go help my neighbors get grounded -
and remove mine / Hi - Dave Vy 73

This thread is exactly why I joined this group. To learn.

With that said, are towers themselves a problem because they are bolted together? If you ground the legs, and make sure the grounding cable is welded to the ground rods, is the friction connection between the tower segments adequate?

I do not believe that bolting them together is necessarily an issue. If you have dissimilar metals, corrosion can set in, though. Then resistance goes up over time and then you could have a problem, if you are implying that you want them to share a common ground. I apologize if you've already explained this in a previous e-mail.

Not sure what you mean by friction. Do you mean resistance? Or are you suggesting that the manner in which you have them connected could be enough for there to be an adequate connection?

Are you able to drop 2 or 3 ground rods around each of the towers? Make the length of the grounding strap less than 75 to 80 feet and drop 2-3 rods per tower. You place them in a spider arrangement.

Sean,

Theoretical only. My 55 ft tower is horizontal. Won't be putting it up till late spring. The grounding thread had produced some questions that I didn't quite understand. It was just a question concerning the efficacy of the physical/electrical connection between the tower sections themselves.

I had the opportunity of being raised with individuals who were wealthy. Although my family was of limited means my friends had really neat toys. I found out that the best way to address the inequality was to just join my rich freinds in the enjoyment of their wonderful toys. They really appreciated that I wasn't talking about their money, just what fun their toys were. I enjoyed their friendship and their toys. Good luck on your Grounding, I am sure that with the information given here you will be able to have a "safe" station. Just make sure that your insurance policy includes both lightning and the station. 73 Charlie KCØBXC North Dakota

Topic: 3726 Message: 3795

Isn't that exactly how a lightning rod works ???

When I first moved here (Abt 19 years ago) I had a small (abt 18 feet) tree out back near a power pole and the power lines and quite a few other very tall (70, 80, 90 feet or so) trees....During one lightning storm this little tree was struck by lightning. It blasted off a couple of horizontal limbs. I liked the little tree so I let it be and hoped that it would recover....Well during the very next lightning storm this same tree was hit by lightning again straight down the middle of the tree from the top. It split the tree in half all the way of its length....Had to cut down the tree after that. There just wasn't much left.....My point is.....

I always heard that lightning would hit the tallest objects before it would hit a lower object...That myth was Busted for me. Also I always heard that lightning never strikes the same place twice...Again myth busted.....There was plenty of other higher objects near this little tree. I was a bit amazed to say the least....

I knew of a guy when I was younger and had a paper route. Well he was walking thru a cemetery one night and he got hit by lightning and killed. They said it hit him in the head and travailed thru his body and exited out of the bottom of his foot. They found him near a very tall tree...The tree was not hit but he sure was....

Then there was the time that I was driving trucks and I was going down the highway and a lightning bolt Struck the road right next to my truck . talk about your hairs standing on end....The blinding light, the crackling BOOM, Well lets just say that is as close to lightning as I ever want to be...I just abt wrecked the Truck....I mean it was right there...another 5 feet and I would have been hit...It's a miracle that I didn't wreck the truck...Talk about a rush.....I'm not all that easy to scare but I can tell you that I was scared outta my mind on that last one...

Another time me and my neighbor were on his front porch and we heard and seen a lightning strike hit the power pole , then it jumped down to the power lines and a big BALL of energy Shot across and down the power lines. Talk about a awesome sight. It was like a ball of blue and white light just shooting down the length of the power lines...We were glad that it was on the other side of the street because they are on a different circuit that we are...Talk about intense....

Bottom line is...Lightning has a mind of its own and you are not gonna change that.
So for me I just feel that the safest and most prudent thing to do is to unhook everything...Period. end of story

It's not nice to fool with mother nature...

Lots of good info with links on the group...Thanks everyone...

Bill In Ohio

The most intense time I had during a lightning storm was when I was a armour Crewman in the US Army Cavalry in the early 1980's. I was a Tank Driver (M60 A3 Combat Tank) Well we had 63 electrically charged rounds (105mm) on board and were in the process of Tank gunnery. Well a nasty electrical lightning storm insued. Well a few of us were a little worried being inside the huge piece of metal During this storm with all these electrically charged rounds...We were told its ok you are all safe. But you better turn off the radios and take your antennas down....Hmmmm. Go figure....

Better safe than sorry I always say...73's and good luck everyone

From: rrath@charter.net
Topic: 3726 Message: 3796

This is a good thread, lets go a little farther. A friend of mine told me about another HAM that saw a lightning storm coming his way. So he turned off the radios, power supply and un-screwed all the coaxs from the radios. He thought he was safe. Well, as the story goes the storm came. A bolt of lightning hit one of the antennas, traveled down the coax to the end of it where the bolt of lightning shot across the room and killed the dog and started the house on fire.

My question would be, would it be better to switch your antenna switch box to one connection that both the center conductor and the shield soldered together and then go to ground? The switch box might explode, but would the bolt also travel to ground? Comments. Ideas.

Rod

Sent: Wednesday, January 16, 2008 8:23 PM
To: ham-antennas@yahoogroups.com
Subject: [ham-antennas] Re: Grounding

Hi Dean, and thanks for the advice.

My understanding is that a good RF ground can make a lousy protective ground, but a good protective ground will also make a good RF ground.

I think I will opt for the lightning ground. However, I was thinking of augmenting the aforementioned configuration with a counterpoise of sorts, in the form of a continuous length of #8 bare copper wire going all the way around the house, both ends terminated together at the common grounding point. That will be about 140' of extra wire near the surface of the ground, perhaps 1/4" to 1/2" deep.

Any thoughts?

Jim

Copper pipe is what I use. I have 10 ¾□ copper pipes pushed into holes I made pounding a ¾ rod into the ground in the bottom of a trench that□s 50□ long.

I use a 1□ copper pipe with 1-3/4-1 inch tees to connect it all up. The trench is a foot deep, so the bottom of the pipes are near 11□ . I set it all up first with the pipes drove in and then soldered it all up. Makes for a good protective ground, and for a good rf ground for my radios. I still use counterpoise for the 4-btv as that□s a totally separate thing, i.e. it□s the other half of the antenna. The benefit of a good ground for the shack is apparent when I use my laptop now. I had lots of noise problems from it before, actually couldn□t use it due to the noise it made. Now with it grounded the rf noise level doesn□t change when I turn it on. As far as lighting goes I always disconnect power, audio, and antennas from my equipt when I log off. I can□t afford to lose my 3 radio□s, their not fancy but with 4 kids money is always short. By the way, since this is an antenna group I thought I should include my antenna thoughts. I currently use a offset feed dipole 135□ long (45□/90□) and the 4-btv. After lots of listening and some transmitting I like the 4-btv much better. The biggest problem and one I expect many hams have is getting enough high enough with the dipole. Its about 30ft and slopes down to 15ft at the other end causing it to be a cloud warmer on all but 6 & 2 meters. The btv on the other hand

has a decent radial system with 32 radials and gets a lot better signal, even on 6 meters (not made for it but it works with 1.3 swr) As soon I as find a used tv tower (free just take it down) which I□ve started looking for, I□ll try to put up some other antennas like hexbeam, spiderbeam, cobweb etc and report how they work.

Hi Dennis,

I really like the idea of soldering copper pipe. It's as bonded as you can possibly get and it's probably a lot cheaper than ground rods. The design that I have drawn up so far requires 17 rods at a cost of over $250.00 for the rods themselves. I think I might ponder the copper pipe thing a bit more before I continue on this quest.

Thanks man,

Jim

That is true at only certain frequencies (low frequencies). All wires have inductive reactance and exhibit some capacitance to ground. So the higher the frequency, the greater the reactance. At some point, what you think is a low impedance to ground, really isn't a low impedance at all. I guess the big question is ...What frequencies are involved with lightning?

Hi Dean, and thanks for the advice.

My understanding is that a good RF ground can make a lousy protective ground, but a good protective ground will also make a good RF ground.

I think I will opt for the lightning ground. However, I was thinking of augmenting the aforementioned configuration with a counterpoise of sorts, in the form of a continuous length of #8 bare copper wire going all the way around the house, both ends terminated together at the common grounding point. That will be about 140' of extra wire near the surface of the ground, perhaps 1/4" to 1/2" deep.

Any thoughts?

Jim

Copper pipe is what I use. I have 10 ¾□ copper pipes pushed into holes I made pounding a ¾ rod into the ground in the bottom of a trench that□s 50□ long.

I use a 1□ copper pipe with 1-3/4-1 inch tees to connect it all up. The trench is a foot deep, so the bottom of the pipes are near 11□ . I set it all up first with the pipes drove in and then soldered it all up. Makes for a good protective ground, and for a good rf ground for my radios. I still use counterpoise for the 4-btv as that□s a totally separate thing, i.e. it□s the other half of the antenna. The benefit of a good ground for the shack is apparent when I use my laptop now. I had lots of noise problems from it before, actually couldn□t use it due to the noise it made. Now with it

grounded the rf noise level doesn□t change when I turn it on. As far as lighting goes I always disconnect power, audio, and antennas from my equipt when I log off. I can□t afford to lose my 3 radio□s, their not fancy but with 4 kids money is always short. By the way, since this is an antenna group I thought I should include my antenna thoughts. I currently use a offset feed dipole 135□ long (45□/90□) and the 4-btv. After lots of listening and some transmitting I like the 4-btv much better. The biggest problem and one I expect many hams have is getting enough high enough with the dipole. Its about 30ft and slopes down to 15ft at the other end causing it to be a cloud warmer on all but 6 & 2 meters. The btv on the other hand has a decent radial system with 32 radials and gets a lot better signal, even on 6 meters (not made for it but it works with 1.3 swr) As soon I as find a used tv tower (free just take it down) which I□ve started looking for, I□ll try to put up some other antennas like hexbeam, spiderbeam, cobweb etc and report how they work.

On the scale of a single thunderstorm, lightning is a discharge--a means of releasing the tremendous electrical energy built up by the storm. But on a global scale, thunderstorms actually separate charge. Lightning and other storm-related electrical features act to maintain a permanent potential of some 300 kilovolts between the earth's crust, which is negatively charged, and the ionosphere (well above 30 miles, or 50 kilometers), which is positively charged. In between, the slightly conductive lower atmosphere allows current to flow between the two regions. Were it not for the constant recharging from thunderstorms, the earth-atmosphere potential would disappear in a mere five minutes.

You would be better off with radials. Put 3 ground rods 10 ft. long on each leg of the tower. Run at least one 10 ft radial out from each rod. The more radials the better off you are. Also run a wire from this ground to the power box ground. If you have more than 1 antenna that is grounded, tie the grounds together.

The idea is not to handle a strike, it is to prevent a strike. With proper grounding, the potential difference between the ground and a cloud does not get high enough to produce a leader.

The best lightning protection is to disconnect the mains, antennas, and grounds from the equipment. Don't forget the rotor cable.

Hi Dennis,

I really like the idea of soldering copper pipe. It's as bonded as you can possibly get and it's probably a lot cheaper than ground rods. The design that I have drawn up so far requires 17 rods at a cost of over $250.00 for the rods themselves. I think I might ponder the copper pipe thing a bit more before I continue on this quest.

Thanks man,

Jim

The trick is to keep impedance as low as possible, so frequency is not an issue. you do that by using wide, flat ribbon, instead of wire, to bong the rods and also to bond the system to the power company ground. Flat ribbon presents almost no impedance. Therefore, the "path of least resistance" rule kicks in.

Again, you should not use wire, as it presents significant impedance to lightning at certain frequencies. The radials and the bonding to the power ground should be made of flat copper ribbon at least 2" wide. The wider, the beter.

The trick is to keep impedance as low as possible, so frequency is not an issue. you do that by using wide, flat ribbon, instead of wire, to bong the rods and also to bond the system to the power company ground. Flat ribbon presents almost no impedance. Therefore, the "path of least resistance" rule kicks in. [snip]

Jim and Group,
My bonding strap used here is a 5/8" wide flat braided grounding strap that has eyelets every 4 inches so you can bolt other conductors to it wherever needed. When I first got setup a friend gave me what was left over on the roll from his installation and it has served me well. I have it entering the shack and screwed to the back of my desk where I run the equipment grounds down to it. The equipment grounds are made from the braided coax shield from RG8 coax. I just strip the shield off the coax, flatten it and install ring terminals to both ends and bolt it to the main ground strap on the back of the desk. My shack ground and AC service ground is also bonded together with the same stuff and so is my tower ground.

If you want to improve the ground conductivity around your ground rods, you can provide a salt well near them. A salt well is nothing more than a plastic pipe (pvc) burried vertically near the ground rods with holes drilled in the pipe so the salt can leach into the ground around it. Leave enough pipe sticking out of the ground so you can put a cap on it and occasionally fill it with rock salt like you use to melt ice off your driveway. I have heard of using copper sulfate to salt the ground with too but don't know if you hcan still get it. It was a dry bluish powder that came in big bags for some reason that I know not, but I read about salting the ground and salt wells in an old book once. I just toss some rock salt on the ground around my ground rods once in a while - this helps increase ground conductivity and also keeps the weeds down around my ground rods !

Rick,

The literature that I've been reading warns against using braided grounding straps. They are good for DC, but not effective at higher frequencies. The recommendation from all sources is to use wide, flat copper ribbon.

Here is one example of what I read about Braided conductors:

"Discard all forms of braided cable. Braid is something a girl does
to her hair. It is not a good RF ground and it's a terrible conductor
for lightning energy."

If you feel that it is a concern then just run a heavy ground wire to
the top and tie the bottom into your grounding system.

Frequency is always an issue, or at least should be considered, when talking about impedance. But it may be that the frequencies are so low that it is not a problem.

Noone is talking about MEASURING the ground resistance with a ground resistance meter. Is this just not done in the amateur community???

Someone, please answer.

This is Why one needs to bond the coax braid to the outside grounding system at the BASE of the tower.. Again with lightning arrestors when it first enters the house to your thick flat cooper Single Point Ground.

I built a Lightning Detector that is tuned to about 300kHz, but
lightning is broadband in a sense.

Ground resistance meters are very costly - over $1,000.00

I understand they are expensive, but one could borrow one or rent one. You could even buy one and check all the hams grounding systems (for a fee, of course.

If you value your house and radios, wouldn't you try to get your hands on one. I bet a lot of hams who think they have a good ground, don't.

I don't have a ground system, but if I had a house with a tower, I would get real friendly with someone, or some company, who has a ground resistance meter. Especially if I had that $10,000 radio!

3814. Half Wave Open Loop, aka dipole bent into a rectangle in the attic

Yahoo group: ham-antennas (2008)
Date: 2008-01-20 23:17:31 UTC
From: Jonathan Helis KB5IAV
Topic: 3814 Message: 3814

I live in an area where putting up an outdoor antenna is a little difficult so I'm experimenting with attic antennas.

I built a 60 foot half wave open loop antenna in my attic. It's basically a dipole bent into a 25x5foot rectangle. Not this best I know, but it will have to do for now.

The antenna is fed with indoor/outdoor foam filled Radio Shack 300 ohm TV twinlead. I had a roll of it lying around so I thought I'd try it. I have a MFJ 911H 1:1/4:1 switchable balun and an LDG Z11 Pro autotuner.

I can load the antenna just about anywhere with a less than 2:1 SWR, flat on some frequencies, and can make contacts. Thhe problem I'm having is even though I have low SWR, sometimes the rig cuts out as if the SWR were too high. It usually happens when I'm running phone at around 100 watts. Sometimes lowering the power helps, but not always.

I've had RF in the shack issues with single wire feed antennas, but the rig didn't do this. I'm wondering if I'm getting some arcing somewhere or if the problem is something else. If anyone has any insight into this, I'd appreciate the help.

The rig is a Kenwood TS-140S.

I found this group while searching Yahoo and thought it would be a great place to ask this question, or any other antenna questions I have in the future.

Look forward to getting a response.

3815. [ham-antennas] Thrust Bearings

Yahoo group: ham-antennas (2008)
Date: 2008-01-20 23:48:33 UTC
From: NS5B
Topic: 3814 Message: 3815

Have my antenna ready, but had a question whether I needed a thrust bearing or not.

The antenna itself is a 7 element tri-bander, and weighs about 58lbs. I'm mounting it to a 15ft mast that is 2.0" galvanized pipe. (Not sure of the weight of that) The rotor is an old HD-73. I refurnished it and it works great, but I'm not sure if it can handle the heavy downward pressure of the antenna AND the mast, and turn efficiently.

Would you not worry about it, take my chances, and run it as it is, or add a thrust bearing? The top of the tower has the tapered section with the mast "sleeve", but I do have another mid-section as well.

If I need a thrust bearing, should I add a ROHN BPL25G Bearing Plate, or use a ROHN BAS25G Accessory Shelf?? Both look a lot alike, except one is TWICE the price.

I have a plate to mount the rotor to, but have nothing for the thrust bearing.

Also, what thrust bearing should I use? I've seen several types from ROHN to Yaesu.

Suggestions??

3817. My inadvertent NVIS test

Yahoo group: ham-antennas (2008)
Date: 2008-01-21 20:37:31 UTC
From: Dave
Topic: 3817 Message: 3817

Well, there you have it. I tried an NVIS antenna. Not the objective of the antenna, but a temporary condition.

I'm rebuilding my wire antennas from windstorm damage. As of sundown Saturday, my 80 meter inverted vee was re-assembled, but temporarily strung only six feet off the ground. As predicted, the SWR minimum was at a lower frequency than when it is hoisted higher, but still within band.

Just for fun, I tried making QSOs on it. Uniformly, my regular contacts reported that I was 4-6 S-units weaker than normal (it's normally strung as an inverted vee with the apex at 50 feet). To contact stations only 200-400 miles away required the use of the kilowatt amplifier on SSB - things were easier on CW of course. On receive, I could hear local stations well enough, but did have to use the rig's preamplifier to do so in a few cases.

So, perhaps six feet is a bit TOO NVIS for 80 meters?

It was an entertaining experiment, though!

Well, I just got my call in April so I'm not an old hat at this, but...

My 80m antenna that got me S8+ plus reports for regional on 100W was a random hunk of wire thrown over tree branches and end-fed from a roller inductor tuner. It's terrible beyond 300-500 miles, but for regional ragchew, it did the trick for me.

However...if the band goes long, it doesn't matter if you have a kilowatt, you'll have issues hearing local people.

I don't have the wire up right now and I've only been monitoring with my vertical, but from what I've been hearing, the conditions lately for regional haven't been too stable.

Maybe it was just conditions, but I wouldn't discount it completely.

Hey everyone,

I have two I.C.E. 318-1B mounting blocks for I.C.E. Series 300 Lightning/Static suppressors. These are designed to attach directly to the top of 5/8" ground rods. I ordered them but never put them to use cause I went with a little different layout in my lightning arrestor system. Also comes with conductive grease. You can check them out at.....

Click here: Impulse Suppressors | Arrestors (http://www.iceradioproducts.com/impulse1.html#5) or....

http://www.iceradioproducts.com/impulse1.html#5 (http://www.iceradioproducts.com/impulse1.html#5) .

I paid about $55 with shipping but am selling them both for $30 plus shipping.

Thanks
Paul

Well, it's going to end up at 50 feet again, as it was before.

I think you're right, though. When I was checking into the
local/regional nets, there was no shortage of locals who were doing
fine. Most of them had their antennas at 20 feet or more. My meager
four feet was simply too-well coupled into the earth!

3824. 75 ohm feedline

Yahoo group: ham-antennas (2008)
Date: 2008-01-22 04:56:53 UTC
From: kb3ccn
Topic: 3824 Message: 3824

ive been searching for all the information i can find on this topic . I would like to use .625 hardline for my vhf/uhf antennas or even QR320 or RG11U . If i adapt the connector or find a 75 ohm connector for this typ of application, will i still be safe with operating my rigs ?

does anyone make a conector for any of the above or do i have to fabricate them my self ..

Thanks

Keith

First, how long will the coax run be ? If it isn't too terribly long - 100' or less, than any regular 50 ohm coax will do, but using 75 ohm coax is perfectly ok - 75 ohms only equates to a mismatch of 1.5:1 swr which is no big deal. Using hardline is a good idea if you need to run several hundred feet, but is overkill on short runs.

[snip]

Get yourself a 31' telescopic fiberglas pole from Jackite - www.jackite.com and enough wire to make a resonant quarter wave vertical for 40 meters and at least 4 quater wave radials. Use the pole to support the wire vertical and spread the radials out on the ground around it like spokes on a wheel - more radials are better. You can also use this arrangement with an autotuner such as the SGC-237, Icom ah-4 etc for 10 thru 80 meter coverage - works great !

3829. Re: [ham-antennas] 75 ohm feedline

Yahoo group: ham-antennas (2008)
Date: 2008-01-22 16:46:31 UTC
From: N9WB
Topic: 3824 Message: 3829

I have used 75 ohm hard line off and on for repeaters. It is available as scraps from cable TV installations. I have used numerous methods of transforming impedance and have concluded that less loss occurs just to pretend that it is 50 ohm and forget about the mismatch. If the antenna is adjustable, antenna adjustments can sometimes be made so the overall network exhibits close to 50 ohm at the transmitter if this is necessary. A 75 to 50 ohm mismatch is very small. Also, the line length can be adjusted to present a 50 ohm match at the transmitter if the antenna is 50 ohms. This can be done by cut and try or the line can be cut to exact multiples of 1/2 wave. This is done using the formula 492/F(MHz) X line velocity factor. This gets very critical at VHF and particularly UHF frequencies.

When a line is exactly a multiple of 1/2 wave, it presents exactly the terminating impedance at the feedpoint regardless of it's own characteristic impedance. It will have increased loss if the line to load mismatch is high, but a 1.5 to 1 is not high.

If you are patient and your transmitter if more picky than most, the line can be run with excess length and then shortened by an inch at a time until a good match to the transmitter is achieved. But again, most transmitters will feed into whatever is there just fine with a 75 ohm line on a 50 ohm antenna.

I would avoid using RG 11 for lengths over 100 ft on VHF and for lengths over 25 ft on UHF. For HF, RG 11 or any 75 ohm cable will work fine, particularly for dipole type antennas. They usually have an impedance of between 50 and 75 ohms anyway. The theoretical impedance of a dipole is 75 ohms but when near the ground (1 wave or less high) or in an inverted vee fashion the impedance lowers.

Most HF verticals have an impedance of 35 to 50 ohms so the mismatch is a bit greater when using 75 ohm line with these. Most UHF and VHF vertical antennas have a matching system to place the impedance at 50 ohms so this problem does not apply there. If the matching system is adjustable such as on a Ringo ranger or a beam with a gamma match the match can sometimes be nudged for 75 ohms.

My thinking is that 75 ohm hard line will present less loss than RG-8 over long lengths in spite of the slight mismatch.

Hello Keith - I misplaced your email and had trouble getting back to you
as I was looking for one callsign and it was under another. Hi, No problem.
I just read Walt's note back to you and wanted to share a couple of simple
thoughts with you also, Many years ago I installed ?" 75 ohm line on a set
of 19 element Boomers stacked at around 85 feet - I was replacing superflex
RG-8 - the gain was tremendous on 2 meters on a run of about 125' and it also
dropped the noise level on the receiver (I can't explain) other than the signal
to noise ratio was dramatically improved -
Some years later I made some transformers for a neighboring repeater group,
I got a couple of connectors from the cable company that fit there cable
(of course) on one end and the other end had the exact thread as a PL-259.
The center pin was only about 3/32"diameter so I used a double male DM-1
(splice connector) and drilled the center pin for the 3/32"wire. It
would screw together perfectly and simply solder the center pin. Worked great
and looked good - Best of luck with yours and you will be very happy with the
results I think - Vy 73 de N?ATH / Dave

3831. Re: Grounding

Yahoo group: ham-antennas (2008)
Date: 2008-01-22 18:32:08 UTC
From: Jim
Topic: 3726 Message: 3831

I don't know anyone in the business and I wasn't having any luck trying to figure out where to rent one. But I did some reading and I'm thinking I could either design one or, use a voltmeter and separate ammeter in conjunction with a constant current source with a variable frequency squarewave. The frequency, as opposed to DC will be required to account for inductance.

The test equipment would have three test leads. The common point is on the ground rod that's part of the grounding system. The two other points you would drive two test rods in a foot deep, located at specific distances from the ground rod, in-line; I still don't know exactly what those distances are. You then send a known current through the ground rod to the farthest test rod and you read the voltage drop across the ground rod and the other test rod. The rest is Ohm's law calcualtions,ut I'm sure they won't be simple...but then, what is?

I think that's how it works but I'm still reading.

The top plate of your tower section probably has holes set for inch measurements. The Yeasu will have holes based on Metric dimensions so you will have to drill some holes, or perhaps just move them a little. I had to drill new holes to fit a Japanese made rotator and thrust bearing I got a few years ago.

3833. long coax lengths

Yahoo group: ham-antennas (2008)
Date: 2008-01-22 22:49:45 UTC
From: ve3diz
Topic: 3833 Message: 3833

I hear about a lot of people using 450ohm to run up the towers (held away from the tower) on hf because it has lower loss than coax. On that thought, is it possible to use 450ohm ladder line for vhf? Would it work better than coax feeding a 2m antenna on a 100 foot tower or would it be best to use a higher grade coax. I'm just thinking that if it would work for vhf it would be considerably cheaper than coax. Any thoughts?

Well being i work for a cable company, i have a truck full of just about anything , and if i need any lenght of feeder , it would not be an issue. Most of my work is all vhf/uhf anyway and may be about 50-60 feet when i get it installed at the new place . I dont want to sound cheap , but if i can make it work , why not use whats free , it will save me about 4-5 hundred bucks when i get everything up i want to and thats the price of new rig :) .

I will definetly experiment with some of this as i get time after my move next week .

Thanks all for the information.

just an FYI , the kb3ccn is the old call and should link to the new one on QRZ , its just going to be a PITA to re regiser for all my groups under the new call .
The new call fits my career field and this topic well :P

Matt,
No reason that 450 ohm line wouldn't work on 2 meters, but you would need a balun at both ends to convert it to 50 ohms. Ideally you would need 9:1 baluns to convert the impedance from 450 to 50, or 6:1 baluns to convert it to 75 ohms which would be close enough. Basically you need to convert the 50 ohms from the radio to something close to 450 ohms, then another balun at the antenna to convert the 450 ohms back to 50 ohms to match the antenna. But then you could design a high impedance antenna I guess that was 450 ohms and direct feed it with 450 ohm line and eliminate one balun needed. You could build a beam antenna for 2 meters that uses a folded dipole type driven element that comes to around 300 ohms and feed it with 300 ohm transmitting line, then use a 6:1 or 4:1 balun at the radio to convert it to low impedance at the radio. This all sounds kind of complicated but really isn't. But unless you have a really long run of feedline, its really not worth the effort. Lots of old timers used balanced feedline on 2 meters and 440, so you might want to checkout some of the older handbooks for antenna designs for the balanced feedlines.

3839. Re: Grounding

Yahoo group: ham-antennas (2008)
Date: 2008-01-23 14:15:48 UTC
From: Jim
Topic: 3726 Message: 3839

Wow! After extensive reading, I've determined that most recommendations for a complete, reliable grounding system are not only impractical for the average ham, but prohibitively expensive as well.

But my findings also suggest a more economical and practical solution might not be a guarantee against damage from a direct hit, but if care is taken, the risk becomes manageable. Not to mention, it can make a good RF ground.

My final design consists of 324 feet of 2" copper strapping, .022" thick, exothermically bonded to eight 5/8" x 8' ground rods and the power company ground. The total cost for all meaterial is almost $700.00 and another $300.00 for an Oxy-Acetyline welder, if I can't rent one.

The layout is in the shape of a hexigon, with one point coming out of it, similar to a single point of a star. My task will be to lower the resistance and impedance to below 5 ohms.

Thanks to all who have contributed to this thread - I really do appreciate the input.

You could also look at the Ozipole, which is the Aussie remake of the
Buddipole! I've just finished building mine yesterday. :-)

http://www.mncarg.org
http://www.timroberts-vk4yeh.id.au/ozipole_construction.htm

What's more, there are two Yahoo Groups about the Buddipole and the
Ozipole:
http://groups.yahoo.com/group/Buddipole/
http://groups.yahoo.com/group/Ozi-pole/

Now I'm not suggesting you especially buy one from Australia, but the
new Ozi (Aussie) design and the established Buddipole (BIG site)
should stimulate the brain cells as far as portable HF ideas go ...
And who knows what you/we all could come up with. :-)

3841. Support rope for wire antennas

Yahoo group: ham-antennas (2008)
Date: 2008-01-24 14:53:17 UTC
From: lecontejoe
Topic: 3841 Message: 3841

Several years ago I purchased two 100-foot lengths of 3/16-in Dacron rope -- as I recall I got it from Radio Works. Since purchasing this rope I've moved four times, including being forced to move by Katrina, and I've used this rope in every place to support a 135-foot, center-fed dipole.

I'm getting ready to put up a couple of wire antennas and need more rope.

I see that Radio Works is advertising Kevlar rope in two diameters:
-- .075 inch, 500 pound test
-- 1/8 inch, 750 pound test

RW's website says the Kevlar rope has a Dacron outer braid to protect it from UV.

RW is still selling the Dacron rope that I am using now.

Anyone have experience with this Kevlar rope?

I was planning to but several hundred feet of the 3/16 Dacron because I've had such good luck with what I have but was wondering about the Kevlar.

Thanks.

I do not have experience with this particular rope, but you might want to take a look at what DX Engineering sells. I have used their product and find it to be very good. It comes in various diameters and either 100 or 500 ft. rolls.

Here are links to a sample of it:

http://www.dxengineering.com/Parts.asp?ID=284&PLID=114&SecID=77&DeptID=40&PartNo=STI-DBR-125-100

I've used the kevlar rope (the small diameter stuff) from Radio Works
and it is good stuff. I wouldn't hesitate to recommend it for antenna
support rope. Mine was an olive color and blended in well into the trees.

The only plate I have right now is the one that the rotor mounts to, and its at the bottom of my "top section". I thought about getting another "accessory" plate like the one that the rotor is mounted to, and mount it at the top, then mount the bearing there (if it could hold the weight and not bend)....then someone mentioned maybe using an actual thrust bearing plate like the ones I mentioned below. The accessory plate would be a LOT cheaper. They run about $50-$60, whereas the thrust bearing plate runs from $129-$159.

Just wanted to ask and see what others used. I appreciate all of the replys on this.

The top plate of your tower section probably has holes set for inch measurements. The Yeasu will have holes based on Metric dimensions so you will have to drill some holes, or perhaps just move them a little. I had to drill new holes to fit a Japanese made rotator and thrust bearing I got a few years ago.

FWIW, I am using a rotor plate with a bearing mounted to it for over 30 years here with no problems. I hasten to add, I have had rotor problems in years past until we left the bearing loose on the pipe so that the weight sits on the rotor. With the weight lifted or supported off the rotor (Hygain) the indicator was very erratic. Letting it float in the bearing solved this problem. Just my experience. I am still today using this same setup with no failures ever. Also, just for comment, I have a ?" diameter copper cable attached to the mast and running down the tower 80 feet to ground. Tied off at each tower section - I'm paranoid about static building up on my antennas and the mast is sitting in greasy ball bearings, Right? That leaves the only true ground following the coax shield straight to my prized rig.

The black Dacron-covered rope is manufactured by "Synthetic Textiles Inc" and is sold by many ham radio dealers. When I went to get my spool of it I shopped for price. At the time, the best deal came from The Wireman.

I used the 3/16" stuff (770 pound rated) to guy a 50 foot telescoping mast. It stretched a trace the first month, I snugged it up, and then it never needed any more attention for five years. I only pulled it all down when I sold that house and moved.

3848. coaxial collinear for 2M

Yahoo group: ham-antennas (2008)
Date: 2008-01-24 21:54:55 UTC
From: G B
Topic: 3848 Message: 3848

Hello,

Going to build a 8 section coaxial collinear antenna for 2M.

A fellow who I respect, told me most of the plans on the internet
were bad. He said only one site had it right. But, as you might guess,
time has passed and I cannot find my notes.

It was something about always an odd number of 1/2 wave sections, and then
a 1/4 wave whip on top, or something like that. The internet shows an even
number and a 1/4 wave on top.

Other guys who have done this mention that they installed ground radials 1/2
wave below the first solder joint for rf decoupling from the feed line.

Does any of this ring a bell with some old timers???

3850. 2.m/70cm Vertical Bazooka question

Yahoo group: ham-antennas (2008)
Date: 2008-01-24 22:48:08 UTC
From: kdf9511
Topic: 3850 Message: 3850

In rummaging around the garage last night I came across a 15ft telescopic painters pole. I thought this would make a great portable mast for a light weight dual band antenna for my HT. I can run it up and get some height while relaxing in the lawn chair and can strap it to the side of my pack frame while hiking. It will also be nice for some ARES work.

Today I started searching around the web for a sturdy dual band antenna that doesn't require any ground plane and came across this one. http://www.hamuniverse.com/ve3vdc2mlittlestick.html It is an is an aluminium version of the Vertical Bazooka design which was made from coax. I saw this and thought it was exactly what I was looking for. I have used an antenna of this design for years on 11m, the Shakespear Big Stick, and loved it. As a matter of fact I will be moding that Big Stick for 10/12m when I get an HF rig.

My question is how well will this work on 70cm? It is scaled for 2m.

I have looked at the twin lead j-poles but have had bad luck in trying to build one of those. I can't find 300 ohm twin lead anywhere around here and just got fed up with them tring to use the older stuff I had in the cable box.

If this one won't work very well on 70cm does anyone have any other ideas execpt twin lead j-poles?

Thanks
Kerry

From: Dave
Topic: 3848 Message: 3852

Collinears with that large a number of elements are *VERY* tricky antennas. Particularly for the VHF bands, you have to get the dimensions exact or the beam will tilt radially upward or downward.

Build yourself an e-probe (a 2" long center-fed dipole soldered to the end of RG-58 coax), and make sure you have a two meter rig available with a REAL S-meter (not a bar graph). Or use any of the diode detector circuits published in the ARRL handbook, etc, and then connect to an analog DC voltmeter. Use that e-field probe to assure yourself that the primary radiation lobe aims horizontal...not up or down. If it's aiming up, you need to lengthen the phasing circuits/stubs. If it's aiming down, it's the other way around. A tenth of an inch makes quite a difference.

Collinears as homebrew antennas have not been popular for this reason - you generally cannot simply build it and have a good antenna. You always have to measure and adjust.

I have used white nylon rope in the past. It dies after 1 to 2 years due to UV and breaks.
So this thread contains some very good advice.

Subject: [ham-antennas] Support rope for wire antennas

Several years ago I purchased two 100-foot lengths of 3/16-in Dacron rope -- as I recall I got it from Radio Works. Since purchasing this rope I've moved four times, including being forced to move by Katrina, and I've used this rope in every place to support a 135-foot, center-fed dipole.

I'm getting ready to put up a couple of wire antennas and need more rope.

I see that Radio Works is advertising Kevlar rope in two diameters:
-- .075 inch, 500 pound test
-- 1/8 inch, 750 pound test

RW's website says the Kevlar rope has a Dacron outer braid to protect it from UV.

RW is still selling the Dacron rope that I am using now.

Anyone have experience with this Kevlar rope?

I was planning to but several hundred feet of the 3/16 Dacron because I've had such good luck with what I have but was wondering about the Kevlar.

Thanks.

Buy your ropes and assoc. hardware at sailboat shops and you generally can't go wrong (except a bit in the wallet department).

3855. Mast

Yahoo group: ham-antennas (2008)
Date: 2008-01-25 19:06:21 UTC
From: Jim
Topic: 1517 Message: 3855

Hi,

I'm putting up a vertical to expand the station's reception to 2GHz. I have a Discone and want to mount it on a mast and raise it against the house, fastened to the exterior, rather than taking a risky climb up 30' to the roof. I have some questions:

Is it advisable to use a metallic mast as opposed to a non-metallic mast? I was considering fabricating one from Home Depot PVC pipe. Another is the safety ground. I haven't found a lot of info on this. If I run a 2" wide length of copper strap from the base of the Discone straight to the lightning arrestor on the ground rod, will I be inviting any extra problems? There are tons of lighting/grounding articles out there, but none that I have found deal specificlly wih that and how that might change the requirements for the mast material.

I hope that all makes sense.

Thanks,
Jim

I'm using one like this made from 300 ohm twin-lead. The overall length is cut for 2 meters, the bottom line is "cut" to 70cm by just putting a small notch in the wire.

Unlike a folded dipole, however, do NOT connect the ends to each other.

I have one of these mounted vertically on a mast in my backyard, and it works great on both bands. I would think a version like that would work well for backpacking.

Good luck!

Ok, that doesn't look quite right after posting, but if you copy and
paste all that into a test editor using a fixed width font, it will
make more sense.

Sorry about that!

I used my discone on a metal mast, and had the mast grounded.
It is small enough that it isn't bothered by the wind to speak of.
Not using it presently, but may put it up for my scanner.
I would say use a metal mast and ground the mast well.
the Discone grounds right to the mast.
YMMV

I bought some sailboat line from shops that sell on ebay. Overall it's rugged stuff, but it's much more stretchy than the dacron-covered stuff that's intended for supporting wire antennas. It's also more abrasive - would damage a tree limb if it went over one, more quickly than the dacron covered stuff.

The sailboat line I got was much less expensive than the Synthetic Textiles stuff, but since it is so stretchy, I tend to use it more for temporary installations.

The sailboat line most certainly is UV stabilized, though - I've had none of it show any sun-related wear in a number of years. Just seems to make a bit of a mess when used with trees instead of pulleys.

3861. Re: Half Wave Open Loop, aka dipole bent into a rectangle in the att

Yahoo group: ham-antennas (2008)
Date: 2008-01-26 21:50:57 UTC
From: Jonathan Helis KB5IAV
Topic: 3861 Message: 3861

I have an update. This morning I started trying to diagnose the problem by removing various parts of my station and transmitting to see if the problem persisted and sure enough, nothing I tried worked.

I then noticed my MFJ 1704 4 position antenna switch wasn't grounded. I connected a scrap of copper wire from the switch to the ground and the rig didn't shut down. When I removed the wire, the rig shut down when I transmitted.

Another thing I did was I used a field strength meter to see if there was RF in the shack and sure enough, there was. When I keyed up with the ground wire not in place, the meter deflected far to the right but when I connected the ground wire, the RF decreased by more than half.

I plan to connect a good wire to the ground and see if the problem goes away. I guess this goes to show why a ham should ground EVERYTHING in their station.

The term sail boat rope or line covers a wide variety of ropes and cords.
Some is stretchy and some is not. It all depends on what the sailor wants the
line to perform.

3863. Coaxial antenna switches and connectors FS

Yahoo group: ham-antennas (2008)
Date: 2008-01-26 23:55:36 UTC
From: Ken Simpson, W8EK
Topic: 3863 Message: 3863

Coaxial antenna switches For Sale:

All have SO-239 connectors.

Para Dynamics PDC 3HD
This is a high quality coax switch, with printed circuit board
stripline type of construction, to keep the impedance constant.
It has the common connector coming out of the bottom, with
the 3 switched connectors coming out of the top.
It looks very similar to the Diawa CS-201 or MFJ 1702, but
is made to switch three antennas. Unused positions are NOT
grounded. $20

Pace 3 position switch
This switch is in a rectangular box. It has the common connector
on the bottom and the three switched connections coming out
of the top. Unused positions are NOT grounded. $15

AmComm JV-104 coax switch
Switches 3 antennas. It is in a nice black rectangular box
Very nice condition. $18

B & W Model 550 A coax switch
This model will switch up to 5 antennas, and does
ground unused antennas. It has SO-239 connectors,
with the coax coming out like spokes of a wheel.
It is in good condition and works fine. $ 35

Waters (B & W) 341 two position coax switch
This switch is very much like the B & W 375 five position
switch, except it only has two position. It has the coax
coming out the back, and it does NOT ground the unused
antenna. This one is in very nice electrical and mechanical
shape. $30

Coax connectors and adapters For Sale:
Prices are per connector. Several of each are available.
These are NOS (have not been used).

BNC male
standard type - $2
crimp on type - $3

Chassis mount BNC female
square mount (uses 4 screws) - $3
screw in type - $4

BNC 90 degree - female to male - $3

BNC "T" - two female and one male - $4

Antenna adapter to fit the BNC connector on the HT
and provide an SO-239 connector that will permit
a PL-259 to be attached. (BNC male to UHF female) $5

UHF Male (PL-259) to BNC female (opposite of above) $5

UHF double female "Barrel connector" (two SO-239 together) $3

UHF "T" connector with two female (SO-239) and one male
(PL-259) connection - $5

UHF female (SO-239) to type "F" Male (as used on cable TV) $5

Type "F" (cable TV) female to BNC male - $5

Prices do not include shipping from Florida.

Thanks.

There is also the fact that some cheap coax will leak RF quite a bit due to poor shielding. And in some instances, without a balun or choke at the antenna end, RF could come back down the outside of the coax.
I didn't have much of a problem with that till the times I tried using my 75 meter dipole on 160 meters by using the inner and outer conductor as an end fed. I didn't have a ground on the tuner, and when I tried to tune up, it actually kicked out the GFCI breaker outlet in the bathroom. Being as all the outlets in my travel trailer, except the one hidden away for the microwave, run throught this outlet. I guess a ground might have helped there as well. I have had no problems with RF in this house. Using a simple ground at the tuner, and the only antenna switch in use is the one ion the tuner.
And I try to keep any coaxial cable jumpers I use as short as practical as well.

I have also found out that the Cable Experts caox I have, at least two sections of it, are rather lossy at UHF. One loses almost all of the power, so has an excessive loss. From about 70watts to less than 1 watt and the other gets about 4 watts maybe at the far end. tests made using a Bird 43 watt meter, and a known excellent dummy load that is virtually 1.0 to 1 at 445 MHz.
So, at 2 meters and up, beware some coax. And do not use the stuff with the foil inner shield for full duplex. This would be like 9913, and LMR 400 and so on.
At ten meters and lower, most coax should be okay, but it might not hurt to test it.
Especially since some has been assemnbled with the connectors only crimped, and I saw some where the connector near fell off, assembled by someone who simply screwed the coax into it and never soldered the shield or center conductor. OTOH, I have an old section that I assembled in the 70's, and other than the insulation in the connector cracking at one end, still tests as okay. But don't get ant moisture in there. Cracks love moisture, and that in turn invites carbon tracks from RF energy... I always tape well any exposed connectors to keep possibl;e moisture out.

And on the ground, double check and see how good it really is. the ground rod I put in here for the electric service turned out to be so good that it was at the same potential as the neutral wire on the service.
Reasonably conductive earth here.
Other places the earth is not conductive enough, and you might need a longer ground rod.
Not sure how to statr a ten foot ground rod in though, unless you do like I sometimes do and water drill down a ways... Works for starting T Posts as well...

YMMV

3865. Carolina Windom Question

Yahoo group: ham-antennas (2008)
Date: 2008-01-27 14:48:18 UTC
From: Jim
Topic: 3865 Message: 3865

Does anyone know if the type of coax used for the vertical radiator of a Carolina Windom is of a specific type? Since the coax is supposed to radiate, I thought that using high-quality coax might prevent it from doing so. Which type would radiate the most?

Jim

3866. Re: Half Wave Open Loop, aka dipole bent into a rectangle in the att

Yahoo group: ham-antennas (2008)
Date: 2008-01-27 17:34:17 UTC
From: Jonathan Helis KB5IAV
Topic: 3861 Message: 3866

I thought I had the problem fixed but when I fired up the rig this morning, the problem reared it's ugly head again. Not sure what to think of this at all.

When I first started hamming in 1989, I ran an attic antenna with a single wire feed that came right into the shack and the only ground I had was the rig grounded to the center screw of an electrical outlet and the homebrew tuner I got from another ham wasn't grounded.

I did have some RF in the shack issues, but never quite like this. My problems were mostly on 15 and 10 meters and occasionally 20. I could work 15, but had to run low power, not more than say 25 watts and 10 was pretty much the same way. The rig wouldn't shut down, it would just act up with the display flickering and so forth. I solved the 10 meter problem with a coax fed dipole but never bothered to do anything for 15.

I'm also having the same problem with my attic mounted AEA Isoloop, with the rig shutting down when I transmit phone. Another strange thing is when I key up the AEA Isoloop, the LDG tuner starts tuning, and it's not in line with it. The Isoloop has a coax feed(Belden RG8/X) running straight to the antenna. I used to occasionally have problems with it, but not as bad as now.

I'm beginning to wonder if perhaps I should switch the feed on my loop to coax, or just junk the half wave open loop and try something new. I've used that design before(vertical as opposed to horizontal), on an apartment balcony and fed it with twinlead and not had the issues I have now. In the apartment, I also had a poor ground and the antenna was closer than the new one and I didn't have the problems.

My ground is an 8 foot ground rod driven into the soil just outside of the shack. I have a copper rod in the shack with the wires connected to it, and a heavy wire running through the wall to the ground rod.

I'm not sure what to think of all this. I just hope it's not my rig going bad on me.

3867. Using a Crossbow to Raise Antennas

Yahoo group: ham-antennas (2008)
Date: 2008-01-27 18:43:05 UTC
From: Marty Bluhm
Topic: 3867 Message: 3867

I recently acquired a small Crossbow. I want to shoot a projectile up and over a 60ft tree to raise a antenna. I've never had any experience utilizing a crossbow. I did not get any arrows, etc with the bow. How do I fasten fishing line onto a small piece of dowel? How do I spool it off the fishing line spool?

Any ideas, greatly appreciated. Complete novice at this.

Thanks and 73
Marty

Why use coax? I use the original design, with a single wire feedline, and it works WELL.

Subject: [ham-antennas] Carolina Windom Question

Does anyone know if the type of coax used for the vertical radiator of
a Carolina Windom is of a specific type? Since the coax is supposed to
radiate, I thought that using high-quality coax might prevent it from
doing so. Which type would radiate the most?

Jim

I'm also having the same problem with my attic mounted AEA Isoloop, with the rig shutting down when I transmit phone. Another strange thing is when I key up the AEA Isoloop, the LDG tuner starts tuning, and it's not in line with it. The Isoloop has a coax feed(Belden RG8/X) running straight to the antenna. I used to occasionally have problems with it, but not as bad as now. [snip]

Try putting an RF choke at the feedpoint of the Isoloop - sounds like the RF is flowing down its coax feedline to the shack. You can make a coaxial choke by winding several turns of the coax into a coil about 6 inches in diameter with about 8 turns. You might also want to get some of the snap on ferrite RFI beads and snap several of them on the coax right at the tuner and at the radio to choke off any common mode currents there. I used to have some RF problems with my Yaesu FT-840 and I fixed it by making up a special coax jumper to go between the radio and the tuner - the jumper has 10 of the slip on RFI beads from Amidon on it then I installed the connectors - no more RF problems !

What kind of feedline are you using on the wire loop that is in the attic ? What you really need to do there is feed it direct with a remote mounted auto tuner like the SGC-239 or 237 and run coax all the way to the shack. Also, keep its feedpoint as far away as possible from the feedpoint of the Isoloop. Do not feed the wire loop with coax and a tuner in the shack - this causes a lot of feedline loss and can cause some feedline radiation - remember the "skin effect" of RF which says it flows on the surface of the wire. Its doing the same thing on the outside of your coax and getting back into your rig that way and is the reason you need to use common mode chokes to keep it off. Radio Shack used to carry some of the snap on RFI beads but was fairly expensive, but if you get enough of them where the feedline connects to the LDG tuner and on the feedline going to the radio it sure cure the problem. The more of them you use, the better they will work ! You also may need to put some on you power cord supplying the DC to the radio as RF can get in on them too. Another trick here is to make the power cord as short as possible or use some of the larger ferrite toroids to wind it through as many times as possible to choke off the RF flowing on it.

Its eithe Amidon or Palomar - don't remember which, but one of them had a free RFI tip sheet they will send you in the mail along with their catalog and you may be able to download it from the web. But it gives you a lot of good ideas into curing RFI problems like you are having Do a google search for "RFI Tip Sheet" and it should lead you to it. RF in the shack can be very frustrating since todays rigs use so much digital and computer control devices, but it can be cured fairly easy.

Good luck OM,

The Carolina Windom doesn't depend on any certain type of coax for the vertical section. It works on the premise that it is an unbalanced antenna and RF lows down the outer side of the coax shield to the line isolator where it is choked off an prevented from going further down the line. So, just use the same type of coax that you plan on using to run to the shack for the vertical section and you'll do fine.

a crossbow. I did not get any arrows, etc with the bow. How do I fasten fishing line onto a small piece of dowel? [snip]

First of all, a simple dowell will not work from a crossbow - you need a projectile with a head on that has a little bit of weight, then you need the fletching (tail feathers) on the rear of it to stabilize it and make it fly straight. Also, if the crossbow has enough draw weight, the doweel can snap in two when you fire it and can fly unpredictably in any direction making it a safety hazard to anyone around - lets keep the hobby safe ! Since you have not had any experience with a crossbow, I would not recommend it for shooting lines over a tree especially if you are shooting toward other folks property ! You would be much safer learning how to effectively use a spincast fishing rig to cast a weight over the tree - just choose the proper direction to keep it from hitting someone or their property in the process. With a cheap spincast rig and a 2 ounce sinker plus a little practice you could put the line over an 80' tree and be a lot safer !

I used a similar method with a bow and target arrow (from WalMart @0.99).

I drilled a very small hole behind the feathers & ran 25lb fish line thru it. Took 2 shots the 1st time but the other 3 trees were right on the 1st time.

After pulling the fish line, i used it to pull up mason line. Then used the mason line to pull up clothes line and finally I used the clothes line to pull up 1/2 inch nylon rope (got it locally for 5 cents per foot).

That did it. HOWEVRER, I would strongly suggest that at the ends of the antenna or the insulators that a retrieval line be attached. Thus if the wire breaks you can pull down the insulator and easily re-attach the wire. Otherwise you might have the rope and insulator stuck in the tree!!!!

Thanks for the suggestion. I may have to try that one. I didn't used
to have many problems on the ISOloop, but now I do. I'm just hoping it
is an antenna/RF in the shack issue, and not the sign of a dying rig.

I'm using 300 ohm foam filled Radio Shack TV twinlead. I tried running
it through 2 different baluns, a 4:1 from LDG and a 1:1/4:1 selectable
made by MFJ and I get the same results. The tuner can tune below 1.5:1
SWR, but the rig will shut down randomly even at low SWR. Grounding the
antenna switch did reduce some of the RF in the shack, but didn't
eliminate the problem.

The feedpoints of these 2 antennas are at least 20 feet apart, so I'm
not sure that is the issue. However, the feedlines enter the shack
relatively close to each other, but not through the same hole.

I've found some snap on beads on the web too I could use, it would save me the trouble of having to make up new coaxes. Palomar has them on their website, they call them split beads.

> Its eithe Amidon or Palomar - don't remember which, but one of them had a

> and computer control devices, but it can be cured fairly easy.

I am very frustrated with this indeed. I've never had an RF in the shack problem like this before. I've used antennas that are less than 30 feet away on HF with a poor ground and didn't have this problem. My first ham antenna was an attic random wire previously used for SWLing that used a single wire feed that came right into the shack. The homebrew tuner wasn't grounded and the rig was only grounded to center screw of an electrical outlet, and I had almost no RF in the shack at all. I could run 80 or 40 at 100 watts with no problems. I could also run on 30, 20, and 17 meters, with the occasional bit of the rig acting up on 20. 15 and 10 were another story as RF was pretty bad in the shack on those bands unless the power was kept low. The problems I had then weren't as extreme as now, the rig just acted up, it didn't shut down.

Among the things I've considered are getting a balun for the feedpoint and using RG 8/X all the way to the tuner since I have a big roll of it lying around, cutting the twinlead so it's only in the attic and using a balun so only coax comes into the shack, even worse trying a single wire feed and seeing what that does to my situation, or just junking the half wave open loop and starting from scratch.

The Isoloop is OK, but I'd like to be able to get down on the lower bands like 40 and have more versatility, like not having to retune every couple of KHZ. When the rig isn't cutting out, I get reports of a good signal, which makes me want to keep this antenna working.

When you have only an attic to work with, it's not easy.

I don't have anything else connected to the rig at present other than
the power supply, code key, microphone, ground, and antenna.

> BTW, you might have mentioned, but what kind of rig are you running ?
> And when you say it shuts down, do you mean that it actually goes off or

>

The rig is a Kenwood TS-140S.

When the rig shuts down, what it does is there's a click and the panel
goes dark then comes back on and won't transmit again for around 30
seconds. The only other times this has happened were a few times I
tried to transmit into an extreme mismatch with the power up high. What
makes this a mystery is I have near flat SWR and it's still doing it.

The power supply I'm running is an Astron RS20. I have it grounded as well.

> I wouldn't trash the loop just yet, I'm sure we can whip this thing !

I hope not as I don't have alot of attic space and that open loop, 25ft
x 5ft was the best I could do with what I had. I haven't been all that
active on HF for the last few years and want to get back into it, and
this loop was what I hoped would work.

I need to keep trying.

Ok, so if the type of coax is not important, then does it matter
which element (short or long) the shield is DC-connected to, through
the balun? My thought was that I should make sure I connect the side
of the balun the shield of the coax comes from to the short element
of the antenna. Or does this even matter?

Any idea how much will be feed-point impedance if I want to feed a dipole off-centered??? Is there any chart which can tell about the impedance value at different points of dipole. I mean, if I want to feed the antenna not at the center but away from the center. If I go say few feets right or left on a dipole from center, how much will be the feed-impedance.

May I suggest using a bow fishing set up. It has the heavy fiberglass arrow that has an attached 90 lb line to a spool that lets the line feed of smoothly. I have used this setup with a recurved bow several times with height to spare.

Ok, so if the type of coax is not important, then does it matter which element (short or long) the shield is DC-connected to, through the balun? My thought was that I should make sure I connect the side of the balun the shield of the coax comes from to the short element of the antenna. Or does this even matter?

Well, the common thought on this is to connect the long side to the hot side and short to the ground side, but in reality it doesn't matter because for a given length of wire the current and voltage will be distributed the same regardless of where it is fed and only the impedance changes. You basically think of it as one single piece of wire when RF is concerned.

Dan

3889. Quick-release radials - suggestions

Yahoo group: ham-antennas (2008)
Date: 2008-01-28 21:56:12 UTC
From: Callum M0MCX
Topic: 3888 Message: 3889

Our little club (callsign M0XXT) often goes out to a field and puts up 40m and 80m verticals with raised radials. I'm looking for a connector that can be used to snap the radials to a home-brew elevated grounding base. We seem to spend huge amounts of time with little nuts, screws and stuff and it never seems to go right. I can make almost anything but I just can't quite get into my head what sort of connector I'm after.

Someone mentioned those battery type connectors that they use on remote controlled models. Sounds quite good because we need strength and heavy-duty (radials tend to tug at the grounding base).

Anyone else got some ideas..?

Callum.

What did you use to make the radials? The weight will probably mandate the type of connector. The RC car battery connectors are probably too weak to support the weight. Whip disconnects might work a lot better.

(radials tend to tug at the grounding base).

Anyone else got some ideas..? [snip]

Have you thought of using the crimp on male and female wire terminals that just plug into each other ? Leave short leads attached to the ground base with one side of the terminals attached to them and the other mating connector attached to the radials themselves - simple plug in solution !

When the rig shuts down, what it does is there's a click and the panel goes dark then comes back on and won't transmit again for around 30 seconds. The only other times this has happened were a few times I tried to transmit into an extreme mismatch with the power up high. What makes this a mystery is I have near flat SWR and it's still doing it. [snip]

Well, it sure sounds like excess RF getting back into the rig to me, and you really need to find out where its getting in at and start there. And its a common misconception that RF problems will be less when the swr is low, but just because the swr is low doesn't mean that RF isn't going to get back into the shack and cause problems. Remember the reason that you want the swr low is so that you have maximum power transfer to the antenna, so with more power getting out can mean that you can even have more of it to get back into the shack to cause problems. Most of the time the RF is coming straight back down the outside of the coax itself right to the radio where it can cause problems. If you can, try winding the coax at the antenna feedpoing into a choke - this is nothing more than a coil of the coax about 6 to 8 inches in diameter with about 8 turns or more of the coax. I don't think this is as effective as using several ferrite beads, but it will help in most cases. Another thing you can try is grounding the feedline from the unused antenna. If you are not using the Isoloop at the time, ground its feedline and ground both the coax shield and the center conductor. This helps bleed off any RF from the unused antenna to ground, then you only have one feedline to worry about, but RF chokes at the feedpoint of the antenna can go a long way into eleminating the RF coming back down the outside of the coax to the radio. But don't be convinced that RF can't be the problem because the swr is low - the more power that goes out means that there is more of it to cause problems ! So your answer will be in finding where the RF is coming back in the the radio and addressing it there - when in doubt, "CHOKE IT" !

Also, how long is the power cable from the power supply to the radio ? If its too long, then it can pick up RF and cause problems too. If you don't want to cut it off to make it shorter, try winding it into a coil to shorten it up.

I agree that it is RF in the shack, but I wonder how it's getting in.
In the past, I ran an attic antenna with a single wire feed into a
homebrew tuner that wasn't grounded, no counterpoise, radials, etc, and
the RF in the shack issue I had was nowhere near this bad. I had no
problems at all on 80 and 40, and only an occasional problem on 20. It
was 15 and 10 where I had the most trouble but this time but the rig
didn't shut down, it just acted up. Now it's on all bands I've tried.
The only ground the rig had was a wire connected to the center screw of
an outlet. I thought single wire feed was most prone to RF in the shack
issues, yet I had fewer with that setup than I do now with twinlead.

I'm going to order some split beads to put on the coaxes, power cord,
and any other place RF could get in. Hopefully that will help.

> Also, how long is the power cable from the power supply to the radio ?

It's probably around 4-5 feet long. I have it bundled up on the desk where my rig is. Another thing to note is when I had the single wire feed, the power supply sat on the floor(small desk), so the cable was stretched out. Again, no RF issues there.

Thanks for hanging in here with me, I'm hoping I'll get this straight soon.

I have seen a flat SWR reading with an analyzer, only to be able to transmit one or two watts. Why? Because the coax shielding was connected by only one or two strands resulting in a very current restricted connection inside a coax connector. The rig will shut down to save it's self.

There are actual test instruments for testing the current handling capability of connections but I have yet to see anyone use one in a ham radio application.

My suggestion is to check all coax connectors once again for possible shield connection problems.

Of course there's RF in your shack. How many feet below that
attic-mounted antenna are you?

Even if you have leaky coax or marginal ground connections, when your
antenna is that close to the shack, it will be the largest contributor
to the shack. The antenna, after all, is an intentional radiator.

For a time there, when I was in California, my vertical was "planted"
outside the shack window. Distance from back of rig to vertical -
four feet.

The TS-140S, like any other solid state rig of that era, cuts back
power gracefully. If the behavior is otherwise, then it's probably
not "RF in the shack" or SWR.

For instance - my Icom IC-735, occasionally goes completely dark for a split second, then the panel lights up again - but the RX is dead. Other times, it cuts out briefly, then comes back on, stuck in TX mode, or stuck in RX mode. What's going on? In this case, I have traced it to a poor DC power connection. When in TX mode, drawing 20 amps, the light corrosion on the power connector causes a brief voltage drop, which causes the rig's microprocessor to go into a bewildered state.

Your symptoms are not indicative of "RF in the shack" (which should not cause that sort of problem anyway) or SWR, but rather something else. I'd start with the DC feeding the rig. If that's the standard six-pin Molex power feed connector of that era, you can squeeze a small flat-blade screwdriver in between the power connections and the plastic connector, and do a little "twist and wedge" to squeeze those female contacts a bit smaller. Also, try a weak acid on the connections (vinegar or diluted muriatic acid) to clean off corrosion. Or just use the Caig De-OXit product to do the same job.

I've seen a lot of otherwise unexplainable rig problems caused by a momentary drop in the 13.8V supply feeding the rig.

Hope this helps.

Jonathan,
Do you have a dummy load you can transmit into ? If so, try it and see if the problem goes away. If it does, then you will be almost 100% sure its RF causing the problem and not a problem with the power supply. Also if you can, try running the rig temporarily on battery power while connected to the antenna - if the problem goes away, then the RF may be getting into the power supply and causing problems. Another thing you will want to do is monitor your supply voltage from the supply to make sure it isn't sagging when transmitting as it could actually be a power supply problem and this may or may not be caused by RF. And make sure the power supply is current rated enough for the rig you are running - most100 watt rigs require at least a 20 amp supply but you probably already know that. Do you get any interference on anything else in the house when you transmit - TV, stereo, or telephones for example ?

It would still be a good idea to inspect the power connections. Rigs
as old as that TS-140 have a lot of hours on those Molex connectors,
which were barely up to the task.

I don't have a dummy load I'm afraid. I'm going to check the cable and perhaps replace it, which is probably a good idea anyway since it's so old.

I do get interference, but that's to be expected with attic antennas and today's poorly shielded electronics.

My power supply is an Astron RS20 20Amp and it seems to work OK. It's not exactly new, but I think it's OK.

It's a one story house, but the antenna is on the opposite side of the house from the shack, probably around 20 feet away at least.

> not "RF in the shack" or SWR.
>

I'm sure it's not SWR, since the LDG tuner can load it down below 1.5:1. RF in the shack seems likely, but when I had a single wire feed many years ago, it did have RF in the shack, but not these problems.

> For instance - my Icom IC-735, occasionally goes completely dark for a
> split second, then the panel lights up again - but the RX is dead.
> Other times, it cuts out briefly, then comes back on, stuck in TX
> mode, or stuck in RX mode. What's going on? In this case, I have

> amps, the light corrosion on the power connector causes a brief
> voltage drop, which causes the rig's microprocessor to go into a
> bewildered state.
>

That shutting down you describe is similar to what my rig does. It will blink and then it won't transmit again until I left off the PTT button for a few seconds.

> Your symptoms are not indicative of "RF in the shack" (which should
> not cause that sort of problem anyway) or SWR, but rather something
> else. I'd start with the DC feeding the rig. If that's the standard

This post has made me think a little. This problem happens when I'm trying to run voice but not CW. The power levels vary more and faster when doing voice than when doing the kind of CW I do, i.e. not very fast and with a straight key. Perhaps the rapid varying of the power may be why it manifests itself.

I may just go ahead and order a new cable for the rig, which like I've said already, is probably a good idea anyway since the cable is so old.

It would still be a good idea to inspect the power connections. Rigs as old as that TS-140 have a lot of hours on those Molex connectors, which were barely up to the task. [snip]

That is so true ! And if thats the problem, you could posibly mdify the radio to have a short pigtail coming out the back with Anderson Power Poles for the connector - much better than Molex !

Ok just a quick suggestion. You already found a ground wire issue with your antenna switch and tested for rf in the shack. Have you tried removing the ground on the switch, cutting back to 1/4 to 1/2 power and seeing if your radio cuts out? Its been said before but a 100 watt radio might be pulling just over the maximum of the capacity of the power supply. Do you have anything else connected that at the same time? Also if you have or can borrow a watt meter. The reason some radios put out more than 100 watts. If that's the case then more current would be drawn and exceed your power supply. Hope that helps. 72 KE7JSL John Sent via BlackBerry from T-Mobile

Gentlemen, I might also suggest that you try and watch the output voltage on your supply while transmitting.
RF can and will deregulate your supply at times - also if you have an output transistor that has opened you
could have near normal voltage on receive and drop considerable on transmit. Symptoms would be the same as the
others have implied, low voltage. Just another opinion.

You mention loops here, and I think wisely so. My guess is that a
small tuned loop will beat any competing, limited space antenna. The
original poster could easily build a tuned loop himself. The most
expensive part he'd need would probably be a good butterfly

capacitor. However, if he'd rather spend money than build an antenna, he could pick up one of MFJ's 936B loop tuners.

I sometimes use a variety of different sized loops made out of 3/4" copper refrigeration tubing, never running more than 100 watts. I tell you, you can get out on these babies. There are some ergonomic drawbacks. In particular, a small, tuned loop will require frequent retuning. A pain in the behind, I know, but a small price to pay for the kind of performance you get.

Anyway, my two cents, I guess. Whatever you do, I hope it works well for you.

From: Dave
Topic: 3906 Message: 3906

Just curious and I realize this doesn't directly involve antennas, but I turned on the rig this evening expecting to work some 40 meter dx and all I could hear was 15 db of pulsating noise. Anyone have any idea where it's coming from or did I miss an earlier announcement? I heard the same noise but to a lesser extent on 20 and even lesser yet on 15. No noise at all on 75/80. Just curious but any information would be appreciated.

Thanks in advance and for the bandwidth.

Hello group,

I'm looking for some help. I am the editor of The SKCC Centurion, the official newsletter of the Straight Key Century Club, and I am looking for articles and how-to pieces for making vertical antennas with fiberglass telescoping poles or using the poles as masts for inverted vee antennas. I am searching the vast information on the internet, but weeding out stuff is laborious.

If you have any articles you would like to share and will let me publish please send them to me. Alternatively, send me links to the information I seek and it may cut down some of my work.

I am looking for a regular contributor for a column on portable operations. If you are interested, please contact me as well.

A WASHING MACHINE???? Amazing but apparently true. We recently moved from NE TN to Eastern VA where we are renting a house while building our house. The rental house is huge -- 3,500 sq ft with an enormous room over the garage -- I have my station set up in this room.

Underneath the station is the laundry room with new LG front-loading washer and dryer that belong to the house (our Maytag washer and dryer are stored in the garage).

I have noticed serious QRN on 40 that wipes out the band. It seems to have no particular pattern -- here today, gone tomorrow. After reading this comment, I asked my wife to crank up the washer -- 40 was nice and quite with the usual atmospherics. When she turned on the washer, 40 was wiped out with "hash" from one end to the other. The noise disappeared when the dryer was turned off. The washer and dryer both have more controls than the cockpit of a 747, thus, I suspect an unshielded, unfiltered microprocessor.

HI Mark,
If you checkout the "Sandpiperaerials" based ibn south wales uk i bought a diy fibreglas vertical from them
at a very good price, what i got was a telescopic pole with a ground stake attached and enough wire to make an aerial for each band you just twist the wire like a helical
mind you it only a mono band antenna , so you have to change the bit of wire to change bands

Hope you have better luck than I did with Whirlpool. They basically told me to piss off they are not covered by any FCC regulation being a microprocessor control application. Reading the regulations I have to agree with them.

They're wrong. FCC part 15 puts requirements on "unintentional" radiators as well as intentional. Heck, the last computer mouse I bought included an FCC part 15 statement that if the mouse causes interference to licensed devices, I may have to stop using it!

And, well it DID cause interference, but since I wanted to use it with my logging software, I just stuck some snap-on ferrites on the USB cable.

The key thing is you have to stop using it. They don't have to fix it.

I've ordered a new cable for the radio. It's a 20 year old cable and
it's probably time it was replaced.

Subject: [ham-antennas] Quick-release radials - suggestions

Our little club (callsign M0XXT) often goes out to a field and puts up 40m and 80m verticals with raised radials. I'm looking for a connector that can be used to snap the radials to a home-brew elevated grounding base. We seem to spend huge amounts of time with little nuts, screws and stuff and it never seems to go right. I can make almost anything but I just can't quite get into my head what sort of connector I'm after.

Someone mentioned those battery type connectors that they use on remote controlled models. Sounds quite good because we need strength and heavy-duty (radials tend to tug at the grounding base).

Anyone else got some ideas..?

Callum.

I got some spilt beads from Surplus Sales of Nebraska today. I ordered
them on Monday and they got here already. I was surprised. I'm going
to try putting them on the coaxes and the power cord and see if that helps.

I've been reading more about common mode currents and I hope the beads help.

3922. LMR 400 Question

Yahoo group: ham-antennas (2008)
Date: 2008-02-02 02:05:42 UTC
From: Jim
Topic: 3922 Message: 3922

Hello all,

I'm trying to figure out how to know when you bend LMR400 coax too tightly. I wanted to do a 2"diameter U-turn, but it seems too resistant for that. Is there a limit to how tight a bend you can put in coaxial cable? If so, where can you go to find that information?

Thanks guys,
Jim

3931. Coax or Ladder Line?

Yahoo group: ham-antennas (2008)
Date: 2008-02-03 15:03:57 UTC
From: kansas400
Topic: 3931 Message: 3931

Hi - I have a proposed installation of an HF antenna set up for use on 20 meters (no higher), and I need a 250 foot run of cable from my third floor to the field next door where I plan to put up both a vertical and a dipole (possibly GR5V) antenna and use that same feed line to feed both - I will just swap out the line at the antenna feed point depending upon which antenna I plan to use each day.

So with a long run like 250 feet, I'm not sure which will work best - coax or ladder line with the following conditions:

- the line will intersect with my metal roof for a few feet where it leaves my house

- the line will need to be buried for 75 feet of the run

- the line needs to be able to feed both the vertical antenna and the dipole (not at the same time).

- budget - say $150 or so for the feedline

Thanks very much for any advice on long runs such as my proposed installation. Thanks. K0EMG Bruce

Bruce,
The type of feedline would depend on the antenna its feeding. You only want to run coax to feed a resonant (matched) antenna. With a 250' run of coax, the feedline losses would be much too high to feed a G5RV or similar antenna where it is not a matched antenna and you would be much better off running balanced feedline that far and use a tuner in the shack to provide the match. You could run 450 ohm feedline to a resonant antenna without using a tuner by putting a 9:1 balun at each end to convert it to 50 ohms at each end. Also, you don't want to burry balanced feedline - it needs to be run in the open to keep it from coupling to other things like the ground which will cause the losses to increase. If your vertical is the 50 ohm trapped type, you could use 50 ohm coax on it and burry it, but antennas like the G5RV would be better served by using the balanced feedline all the way to the shack.

OK, thanks for the different answers.

For the 40m antenna, I'll get some of those "remote control battery connectors" and use a small cable-tie to clamp it together.

For 80m, I first check on the strength of the 40m version otherwise I'll down Danny's route of a base plate that I can bolt directly to.

Thanks,

Callum.

> I never
> knew that radials had that potential!

If you think of the radials as "the other half of the dipole" (and perhaps even if you don't) ...

There is a current along the length of the vertical, which varies with position along its length, approaching zero at the end. Along with that, there is a voltage that varies with position too.

Likewise, you are sending an equal but opposite current into the radials, so you are going to have a current and a voltage that varies versus position along the radials too.

All this means so far is that the radials don't have zero voltage everywhere. They are not "ground!"

If you feed the antenna with coax from a grounded rig, and if you don't have currents on the outside of your coax, then the voltage at the end of the coax, where it connects to the radials, will likely be low. Presumably the radials are a quarter wavelength long. That means the voltage out on the ends of the radials is going to be maximum ... just like it is at the very top of your vertical.

In general, the end of a wire is a point of current minimum and voltage maximum.

This is a rather simplistic view of things, but I think it applies.

Andy

A "radial field," as in buried radials, is a different animal. Those radials are in contact with the earth everywhere along their length, and that makes them totally different than the elevated radials in the subject in question.

Elevated radials might be just as "hot" as the so-called radiating element itself, and should be treated with similar caution.

I don't know; that's a good question. (Anyone know?)

I'm told that pinning or laying the radials on the earth, makes them more like buried radials. It detunes them, probably makes their length uncritical, and may add loss to the antenna system depending on how many radials and what kind of ground you have, because more RF energy is coupled into the lossy soil.

Personally, I might be hesitant about having exposed wires where children or pets may be playing, for both electrical and physical (tripping safety) reasons. But mostly it's a big "don't know" whether it is really unsafe.

Andy

I would think as long as their inductance is low, there would be minimal voltage dropped. In other words, if someone had one foot on the ground and one foot on a radial, it should be relatively safe, if I understand it correctly.

I know when I designed my grouding system, I read loads of material and it all basically talked about keeping inductance low to provide a low resistance path for RF and lightning. Another thing that I came across was a statement that buried conductors exhibit very little or no inductance to RF, due to their contact with the ground.

I hope I didn't make it more confusing.

All of the above is correct. If you insist on putting the radials
on-ground or just below ground, the requirements for simulating a
solid copper sheet go up dramatically.

If there is enough voltage at the end of the radial to arc to ground,
then it is a sure sign of two things - the radial is not well coupled
to the earth, and you need a lot more of them so that you can get that
coupling.

By happenstance, I managed to get my vertical elevated...the prior
owner of the house had built a lifted wooden fort for his children.
It's about 12 feet off the ground. The vertical went in there.
Happily, that fort is situated at the intersection of two fences.
Therefore I could string three radials outward from the antenna, and
they would simply be situated directly above the fence line, where
nobody would attempt to walk anyway. Some 4 X 4 posts appropriately
placed allow the radials to be elevated high enough off the ground
that where a fence gate exists, even the local farmer's tractor can
make it through without touching the radials.

The performance of this elevated vertical is dramatically better than
when it was on the ground.

Hi Dave,

>>> the radial is not well coupled to the earth,

You'll need to explain that one because being raised, I guess I don't want that?

Anyway, we ended up raising them by extending the radials with heavy duty nylon cord and it worked a treat.

C.

All of the above is correct. If you insist on putting the radials
on-ground or just below ground, the requirements for simulating a
solid copper sheet go up dramatically.

If there is enough voltage at the end of the radial to arc to ground, then it is a sure sign of two things - the radial is not well coupled to the earth, and you need a lot more of them so that you can get that coupling.

By happenstance, I managed to get my vertical elevated...the prior owner of the house had built a lifted wooden fort for his children. It's about 12 feet off the ground. The vertical went in there. Happily, that fort is situated at the intersection of two fences. Therefore I could string three radials outward from the antenna, and they would simply be situated directly above the fence line, where nobody would attempt to walk anyway. Some 4 X 4 posts appropriately placed allow the radials to be elevated high enough off the ground that where a fence gate exists, even the local farmer's tractor can make it through without touching the radials.

The performance of this elevated vertical is dramatically better than when it was on the ground.

(Crackers? Well, you and me for a starter James, closely followed by Tim and Aidan :))

I'm about to buy a 200 meter length of PVC coated FlexWeave from a friend of mine who owns an antenna company. As we know, field events need something resistant to tangles and will be happy to be put up and down regularly. Is this FlexWeave a UK variant of another brand available world-wide..?

For instance, see <http://www.wsplc.com/acatalog/Antenna_Cable.html> http://www.wsplc.com/acatalog/Antenna_Cable.html and look for PVC-50 PVC Covered Multi Stranded

Callum.

Yes, if your goal was raised radials,then you do not want them coupled to the earth. The benefit that arises from elevating the radials is reduction in ground losses. If they're raised at the vertical, but taper down towards the earth at the ends, then you can, indeed, have a flashover risk.

ON4UN's book "Low Band DXing" has a wealth of experimental data on transmit verticals with a comprehensive treatment of grounded verticals versus counterpoises (elevated radials).

That's a fine way to get the radials off the ground.

In my case, I end up having to attach something (radial or rope) to a tree or a planted pole, because we're in lush green growing agricultural country, and whatever I do, it must remain tractor-friendly for purposes of mowing the weeds. A wire tapering towards the earth is too easy to not see, and the fellow who does our mowing will be 96 in March so I wish to respect the condition of his eyesight!

How far ir this antenna base from he ground? Do you have a ground rod connected to the base in addition to the radials? If not do so. You need ti anyway for lightning protection.

This may cool things off.

I don't know; that's a good question. (Anyone know?)

I'm told that pinning or laying the radials on the earth, makes them more like buried radials. It detunes them, probably makes their length uncritical, and may add loss to the antenna system depending on how many radials and what kind of ground you have, because more RF energy is coupled into the lossy soil.

Personally, I might be hesitant about having exposed wires where children or pets may be playing, for both electrical and physical (tripping safety) reasons. But mostly it's a big "don't know" whether it is really unsafe.

The base was 21 feet from ground and the radials ended up being about 18 inches from ground. Seemed to work great.

Ground rod connected to radials? No - this wouldn't work, the point is that I don't want it grounded at all?

I do actually have the Low Band DX book, I may get it back out tonight and read about this topic.

Actually running a wire from a ground rod to where the radials connect to the coax will not harm the resonant affect of them at all. If you grounded them at the ends, that would be a different story.

Being elevated that much, they will be hot just like the ends of the side of a dipole that attaches to the coax shield will be hot. I agree that the antenna will be much more efficient with the radials elevated in this manner.

Ah, but you do not connect a ground rod to the side of your dipole
that is tied to the coax shield. That would make it a different antenna.

For static drain purposes, a ground rod may or may not be a good idea.
A lightning protection system is exactly that - a "system". Randomly
adding a rod in the wrong spot may actually increase your risks in the
event of a lightning hit. Although I would acknowledge that
typically, rods planted out in the antenna field are not the ones that
increase the fault currents inside the home.

If you run a wire from the "radial" end of the vertical to a ground
rod, and that wire conducts any RF current, then you have just changed
the characteristics of the antenna'a radiation pattern. If electrical
code requires this connection to be made, then do it through an
inductor, so that the presence of the wire does not degrade the
vertical's performance.

An elevated vertical is, indeed, like a dipole - you want the two
connections to the vertical to be floating, neither grounded. Purists
go so far as to use a sleeve balun on the feeder coax.

In my case I admit I'm relying on good providence - we don't get
lightning in my area and I've done nothing about grounding for
lightning safety. If I still lived in the midwest, I'd take it a lot
more seriously.

Tried the new power cable today, rig still shutting down when I try to transmit SSB. Beginning to wonder if I should junk the twinlead and go for coax or even single wire feed. I once had an antenna with a single wire feed and never had this problem, and those are supposed to be the worst for RF in the shack issues, if that is the problem.

I've also snapped split beads on the coaxes and the power cable from the power supply to the rig and that hasn't helped. Wondering what else to do.

Just outta curiosity, i havent been following the post , but by chance are you trying 40 meters with a switching power supply for the rig?
my situation is Kenwood TS-140 and Yaesu Ft-100d and a Radioshack 25 amp switching powersupply . Any kind of 40 meter at all above 3 watts causes the ciricutry in the pwr supply to lose timing cycle and shut off . Going back to a Transformer Based pwr supply . full 100 watts both radios , and full 100 watts CW both radios on to a common fed 4 band dipole (300 ohm twin lead) and mfj-949c tuner.

3976. Tuning up a ground-mounted vertical

Yahoo group: ham-antennas (2008)
Date: 2008-02-06 14:36:17 UTC
From: w2nsf
Topic: 3976 Message: 3976

Hello. I've been struggling with which of two methods to use in tuning up my ground mounted vertical antenna system, which has a feedline choke at the base and 32 radials. What I did initially is measure the SWR in my shack, at the end of my 85 feet of feedline. I reasoned that the impedance that my transceiver saw there was more representative, as I was "tuning up" my entire antenna system. Then, I heard from an expert that this was not a fair tuneup of this antenna, and I should have used a short coax pigtail and tuned it up right at the antenna itself. His arguement was that the generous bandwidth I saw at the end of the coax falsely represented the antenna's actual performance. This is what I think I know: a low SWR of my entire antenna system (antenna plus feedline) means a "happy" transceiver output stage, and more energy is being transferred to the system. Of course, if that energy is not radiated efficiently by the antenna itself, then even though my transmitter's output stage is happy, I'm not radiating all the energy I can, and that, of course, is not a good thing. Can anyone help me here? Thanks, 73, Jim, W2NSF

Jim,

Don't know what you are using to tune you 'tenna but if you have access to a AIM-4170 analyzer you can have it both ways. The analyzer is intelligent enough that it can "remove" the coax from the testing while testing through it. You tell it about your coax and it figures out what to eliminate from the testing figures and effectively tests the antenna without the coax influencing the figures.

Think of your feed line like a Truck... You just dump your RF onto it and drive to the antenna. You may loose a little on the way but not much. How far ? With LMR 400 you can go a long way before you loose enough to worry about. The Coax is not a tuned part of your antenna system.

The Buddipole only appears to be a symetric dipole... the 2 coils are actually wound differently, and the instructions have you tap them at different settings... producing an off center fed antenna with closer to 50 ohm loading. They also sell a balun which can allow symetric set-ups.

The Buddipole works well. But for more permanent stealth set-ups I would recommend two alternatives... the Par End-Fedz (see www.eham.com reviews) which are tremendously efficient (and cheap) end fed wire antennas, or the TW-2010 which is a compact capacity hatted vertical dipole which I can set up inless than a minute, and which, even when set up inside, is terrifically effective. If you don't have a way to hoist a wire antenna the "jackite" poles listed on E-bay are a very good solution.

The Buddipole only appears to be a symetric dipole... the 2 coils are actually wound differently, and the instructions have you tap them at different settings... producing an off center fed antenna with closer to 50 ohm loading. They also sell a balun which can allow symetric set-ups.

The Buddipole works well. But for more permanent stealth set-ups I would recommend two alternatives... the Par End-Fedz (see www.eham.com reviews) which are tremendously efficient (and cheap) end fed wire antennas, or the TW-2010 which is a compact capacity hatted vertical dipole which I can set up inless than a minute, and which, even when set up inside, is terrifically effective. If you don't have a way to hoist a wire antenna the "jackite" poles listed on E-bay are a very good solution.

From: Chris
Topic: 3976 Message: 3983

O.k. so it's a vertical, is it just a plain 1/4 wave radiator or is it
a multi-band? Does it have linear loading or traps?

Are you wide band tuning it or using it for a dedicated and resonant band?

More info to be able to give you better advice.

On Feb 6, 2008 9:36 AM, w2nsf <schulstrasse23@...> wrote:
> Hello. I've been struggling with which of two methods to use in tuning up my ground

> What I did initially is measure the SWR in my shack, at the end of my 85 feet of
feedline. I

If it is say a 20m vertical and you are trying to wide-band tune it,
you would be better served to put the tuner at the feed point of the
antenna, particularly feeding with coax and using ground radials
rather than elevated. The SWR will be high as you move out of the
band and you want to minimize the losses.

Depends a lot on what you specifically have and what you intend to do with it.

The Buddipole works well. But for more permanent stealth set-ups I
would recommend two alternatives... the Par End-Fedz (see
www.eham.com reviews) which are tremendously efficient (and cheap)
end fed wire antennas,[snip]

They all work well, but if you have a good tuner, you could just use an end fed halfwave wire and do the same thing, Not much to it, just cut the wire one half wave in length by using the formula 468/freq mhz = length in feet, then string it up and connect it to the tuner. It will also work on bands that are harmonically related. SO a wire cut for 3.5 mhz will also work on 7, 14, 21, & 28 mhz. Even with high copper prices wire is still cheaper than commecial versions !

Thanks Dean. I was reading about a dipole where the feedline was to be of a certain length and I couldn't figure out why. I'm not gonna worry about it.

1) With a ground-mounted vertical, the choke balun on the feeder is probably doing nothing...but it doesn't hurt.

2) 85 feet of larger-sized feedline (RG-8, RG-213) introduces low enough loss that if the vertical is close to properly tuned, your in-shack SWR and bandwidth measurements are close enough to get you where you need to go.

3) If you have to stand near the vertical to use the MFJ-259 device, then you will disturb the vertical's tuning with your body to a greater extent than the error caused by measuring through the feedline.

4) Get a PC. There's so much free stuff that's beneficial for ham radio that you really do need one. You don't need much of one. Our family's computing needs are covered by several Macs, but I still got a PC for ham radio. I spent $100 and got a fairly modern 2.8GHz Pentium 4, Windows XP, and a 19" CRT monitor. For free, you could get

about an 800MHz Pentium III with Windows XP and a 17" monitor. Use your local Craigslist to find one. Put free AVG virus scanner on the PC and then you'll be at no risk for connecting to the 'net or whatever. Bonus - now you can play ham radio with the computer involved for logging, DX spotting, etc, to your heart's content, without stopping the rest of the family from using the Mac.

From: Callum M0MCX
Topic: 3987 Message: 3987

Whilst we're all thinking about verticals recently, a thought occurred to me of feeding an elevated radial vertical with open wire feeder, I assume one can work out which is the "hot" line of the feeder - and feed the vertical radiator with it - and feed the radials appropriately near the base of the antenna with the other half?

In an ideal free-space world, both sides should have equal currents.
There isn't (well shouldn't be) a 'hot' line with ladder feed. It
shouldn't make a difference.

Actually, for all practical purposes, when you buy the ladder lline, which usually comes in a roll, :-), you could just spray paint one side while in the box and the edge would be visable. Then when using for a project that requires that the line be polarized you have a reference. Can't think of any projects at hand, but sure there must be some applications.

3995. Re: Radials flash-over

Yahoo group: ham-antennas (2008)
Date: 2008-02-07 02:36:42 UTC
From: Bryan
Topic: 3949 Message: 3995

Hi James,

I like your thinking but if you're gonna think big, think REAL BIG! I envision a half-wavelength over a quarter-wavelength w/ a quarter-wavelength phasing stub w/ quarter-wavelength radials, elevated by a very large helium-filled blimp... 5.2dBd gain, IIRC. On 160m, it'd *only* be 266' + 133' = 399' tall (plus another 133' for elevated feed)... 532' to the top! Hmm... might need the 'Goodrich Blimp' to hoist it! hi!

3999. Re: [ham-antennas] Re: Feedline Length

Yahoo group: ham-antennas (2008)
Date: 2008-02-07 04:14:36 UTC
From: Andy
Topic: 3975 Message: 3999

> Thanks Dean. I was reading about a dipole where the feedline was to
> be of a certain length and I couldn't figure out why. I'm not gonna
> worry about it.

There are some HF antennas where the feedline IS part of the antenna (where the feedline itself radiates) and it is supposed to be a particular length. And there are other antennas where the feedline performs an intentional impedance transformation. In either case, size ... oops, length ... matters!

In general, if the SWR is moderate (not near 1:1) at the antenna, the length of feedline will determine the impedance seen at the shack. Say if the SWR is 4:1. If you use "any" length of 50 ohm coax, the impedance might be anywhere from 12 ohms to 200 ohms depending on the length you choose. It might or might not matter (since they both have the same SWR). Only if the SWR is 1:1 to begin with, and if the feedline has low loss, does the length not matter.

Regards,
Andy

4001. Marine installation (remember the flashing over radials?)

Yahoo group: ham-antennas (2008)
Date: 2008-02-07 09:47:45 UTC
From: Callum M0MCX
Topic: 4001 Message: 4001

Further to the thread regarding my radials flashing over, I have all of a sudden become worried about an installation I shall be doing to a 70 foot steel boat which is currently being built for me. I am planning on being QRO with an SGC amplifier and matching SG-235 QRO tuner / coupler.

I shall ground the tuner firmly on the hull and send a "hot" wire up a Shakespeare Marine vertical.

If my 80m radials flashed over last weekend or so, what's to stop us all frying on the hull..?

Callum.

4002. Re: Tuning up a ground-mounted vertical

Yahoo group: ham-antennas (2008)
Date: 2008-02-07 10:12:55 UTC
From: steve95446
Topic: 3976 Message: 4002

The coax may definitely make your SWR look a lot lower than it really is at the feedpoint. I had a 35ft length of RG58 feeding an antenna and there was a very obvious difference in SWR when using a short coax "lead" to the MFJ at the feedpoint and then at the shack.

If you are trying to "dip" the antenna to tune it to a particular point in the band then it probably makes little difference, but if you want to know the absolute SWR then a reading at the feedpoint is better.

For antennas where the length of coax has a dramatic effect on the tuning - such as the G5RV - then I guess reading at the shack end tells you the SWR of the whole system.

When I tried a G5RV, the reading at the bottom of the matching open wire feeder was drastically higher than measured in the shack. But what are you supposed to do about it?

I wasn't impressed by the G5RV apart from local work on 40m and 80m.

By the way, I have a design for an attic-mounted stealth antenna that works well at www.qsl.net/g0kya

I have always used what i needed to get from the antenna to the rig.
LMR-400 for hf is serious over kill though and your biggest issue will
be the wieght of it suspended from your antenna in the air.

4004. Re: Tuning up a ground-mounted vertical

Yahoo group: ham-antennas (2008)

From: w2nsf
Topic: 3976 Message: 4004

I'm following up here with more information to add to my original post.

Thanks for all the great replies, except from you PC guys ;-)

The antenna is a Hustler 5BTV. That means it's basically a trapped vertical, except for the 75 meter resonator on top and whatever that DX Engineering 17 meter kit is doing. It's fed with Davis Buryflex, which claims the same performance as LMR400, but somehow I doubt that. The antenna is located about 100 feet from a salt water body of water and it is very quiet, when I A-B it with my dipole.

I started with the measurements that came with the Hustler antenna and only had to change the 20 meter setting a little. The rest of the antenna just sort of fell into place, after I got that setting adjusted. Of course, I had to dick around with that funny-looking 17m kit thingy, but it's settings didn't affect the rest of the bands at all.

My goal is antenna efficiency and I'm trying to get maximum bandwidth around the middle of the phone part of each band. I don't operate much CW, but I do operate some RTTY and PSK31 once in a while.

I was happy with the SWR 1.5:1 bandwidths I got when I measured the SWR in the shack, but then someone burst my bubble when they told me these were not "true" readings and I should have been measuring SWR at the antenna feedpoint.

So, I am still struggling with the concept of having a nice, low SWR at the shack, which means to me that I'm getting an efficient transfer of energy from my transceiver into my antenna system. But, if my transceiver and feedline are happy and my antenna isn't radiating effieciently, then I guess I should bite the bullet and go measure the SWR at the antenna, standing a reasonable distance away, of course. It's just it's SO COLD out there, right now, HI HI.

Thanks to all of you for your help, even you PC folks ;-)
73,
Jim, W2NSF

Me too, I agree.

For your purposes and that vertical, just tweak things with your tuner in the shack and go.

I run a GAP Titan and though it's < 2:1 where it should be, I use the auto tuner in my rig to put the polish on it. Works fine.

It is nice to have the vertical to switch with my wire. The noise levels are drastically different with the vertical generally being much quieter at my QTH. It's interesting to note which one is working better for me on a particular day too, as that definitely changes around depending on propagation at the time. On the same band on a net sched, I have random days when either vertical or G5RV will work better for me.

If you can sneak a piece of wire up over there, go for it, you'll enjoy the flexibility to switch around.

4009. Short Mast for a G5RV

Yahoo group: ham-antennas (2008)
Date: 2008-02-07 16:36:46 UTC
From: karl.moll
Topic: 4009 Message: 4009

I'm in a rather restricted situation. My community is covered by CC&Rs. I have no trees on my property, and I'm in a single story house. At best, I can mount an antenna on the peak of my house which is about 20 feet up. I've been thinking of adding a 10 to 15 foot mast to get me up higher. The mast must be very unobtrusive because of the CC&Rs. I've been thinking of using 1/2 inch schedule 80 pvc pipe, but am having trouble finding it in that wall thickness. Regular schedule 40 will whip around entirely too much for this application. Can anyone recommend a non-metallic mast that is thin (less than one inch O.D.), neutral in color and stiff enough at 15 feet long to support an antenna? The ends would be attached to my fence to give me an inverted "V". Thanks.

Yes, Sched 80 is hard to find, you might try getting a wooden dowl large enough to fit inside the sched 40 to strengthen it.

Not exactly meeting your criteria, however I figured I'd toss this out there.

I recently put a dual-bander up using top-rail from hurricane fence.

They are sold in 10' sections at Home Depot and are very inexpensive, maybe $9.50 a length I paid locally.

I sheet metal screwed the sections at the slip joint they have, placed the base on a shed roof section on one end of the house and bracketed at about the middle of the two pieces on the gable fascia. Very very solid even with a 17' dual-bander on top.

It's nowhere near as visible as it sounds. Unless you are purposely looking for it, you would never notice it just driving by my place.

Top-rail is galvanized, but you could scuff it up and paint it to match the color of the house if you want or a light grey so it won't stand out as much.

As far as non-metallic, simply suspend the wire with some nylon and an egg insulator so it stands off the support a bit and you should be fine.

Karl,

Go ahead and use the sched 40, but put wooden dowels inside it to give it the strength that will keep it from flopping around in the wind. Wooden dowels are inexpensive at Home Depot, Lowes, or ACE Hardware.

4017. RE: [ham-antennas] Marine installation (remember the flashing over radials?)

Yahoo group: ham-antennas (2008)
Date: 2008-02-07 23:21:14 UTC
From: James Thresher
Topic: 4001 Message: 4017

I've been looking into this and both the SG-230 and SG-235 Manuals suggest to use the steel bulkhead as the ground connection on boats, I don't know why this would behave differently to the tuned radials (Perhaps the fact that they are tuned could have something to do with it, hopefully someone else can explain why this would be the case).

As the SG-235 is the higher power version I'm sure they wouldn't recommend using the hull as the ground if there was any risk involved.

James

Subject: RE: [ham-antennas] Marine installation (remember the flashing over radials?)

I was hoping for a reply to this one.

Basically, why will the hull act like a ground / radial system whilst not
flashing over to us humans (well, I hope it won't!) like my 80m elevated antenna system did?

Anyone?

Callum

Subject: [ham-antennas] Marine installation (remember the flashing over radials?)

Further to the thread regarding my radials flashing over, I have all of a

sudden become worried about an installation I shall be doing to a 70 foot
steel boat which is currently being built for me. I am planning on being QRO
with an SGC amplifier and matching SG-235 QRO tuner / coupler.

I shall ground the tuner firmly on the hull and send a "hot" wire up a Shakespeare Marine vertical.

If my 80m radials flashed over last weekend or so, what's to stop us all frying on the hull..?

Callum.

From: QRP_1@juno.com
Topic: 4013 Message: 4018

Standoffs would be better and use insulated wire too. But instead of a dipole, you could do a loop completely around the house on standoffs under the eaves of the roof. Feed it with some cheap 300 ohm twinlead and a tuner for multiband operation.

I would just get some cheap light TV antenna mast and an eave mount bracket for it, and paint the mast gray. 3 sections of the mast will give you 30' in height and provide a direct ground path for lightening as long as you bond all 3 sections together. You can get them at Lowes and Home Depot.

Callum,
I'm operating /MM from a large steel-hulled vessel in the South Atlantic off the coast of Angola. I have my FT-857D in my cabin & about 50 ft. of RG213 running up to an SGC-230 autotuner on the roof of the bridge. The antenna is around 20 ft. of insulated 8SWG wire running almost vertically. The whole system is tuned against the steel structure of the vessel which is at the same potential as the sea as it's sitting in salt water.
The ship's 400W HF radio is using the same set-up with an Icom autotuner & a 16ft. Shakespeare whip.
The ship itself is at ground potential, which is the same as the salt water it is sitting in.
As long as your vessel's hull is also at the same potential as the sea then you've got nothing to worry about as your radio ground will be (or should be if you've grounded everything properly) will also be at the same potential.

Thanks Rick and I do need to bury the cable for about 50 feet of the run, so that being said, what if I just put up a 20 meter dipole and feed with coax. It's still a long run of coax (about 200-250 feet in total), so I'm not sure what the best coax would be to purchase within a $150-200 budget (I can't afford to do hard line that far). Is there a recommended coax that's good for long runs and can be buried for part of the way without too much loss at 14 mhz?

Thanks.

Talk to your local Cable TV guy.... Take him out to lunch...They take
have end roll chunks of 75 ohm aluminum cable. It is just salvage
to them and you may get it at the right price. You can make your
own ends just look in some old ham books. If you don't want to
burry it directly in the soil just get a hunk of one inch cheep
plastic water pipe and slip it inside.

The cable industry uses a jacketed cable with a stick fluding compound between the cable and the jacket for underground runs with out this the aluminum jacket will disolve in less than a year. you might be able to gety away with putting it in conduit "I wouldn't do that unless the conduit was completely water tight" besides that that is a good idea I don't have the exact spects for 14 mhz but the chart that I have shows .500 cable loss at .16 db per 100 ft at 5 mhz and .40 db per 100 ft at 30 mhz and .750 cable loss at .11 at 5 mhz and .26 at 30 mhz and .875 cable loss is .09 at 5 mhz and .23 at 30 mhz this is for foam dialectric hard line.
hope this helps.

DavisRF makes and sells "Bury Flex", a buriable low-loss coax. Foam dielectric, so you don't want to kink it or step on it, about 30% less loss than solid dielectric. 81 cents per foot in your quantities. The Wireman has a direct bury capable RG-213 for 71 cents per foot. The "Bury Flex" is lower loss. Both companies are very ham-friendly and easy to work with; phone orders tend to work better than email orders.

At 200 feet, you're going to have about 2dB loss at 14MHz with any of the foam 50 ohm 0.405 inch cables, and about 2.7dB with any of the solid-dielectric cables. Not a big issue unless you're trying to be a top ten contest station...after all, most hams with big antennas have long coax runs, too.

From: chuck54875
Topic: 4027 Message: 4027

Hi guys,

I'm new to the group. I've always delighted in experimenting with different Amateur antennas of all kinds but recently acquired a beam.

2 questions:

First: I've been using verticals and dipoles for close to 30 years and the dipoles have always been mounted at about 30 feet or more at the apex with good results. I've just picked up a Cushcraft MA5B Mini Beam which is designed for 10/12/15/17/20 meters, but the highest I can mount a beam (without going to a tower, which I can't do here) is about 18' to 20' off the ground (rooftop tripod mount). I'm not familiar with beams and wonder how badly the "low" height will degrade performance? Opinions appreciated.

Second: I'd like to get recommenations for a rotor interface to with the beam. My PC is Windows XP based, and the radio is a Yaesu FT-950. I have a medium duty rotor that should easily handle this mini beam but have no concept as to how to use an interface. From quick reading, I understand the antenna control is done through whichever logging software your using. I have no preference as to a logging program and will use whichever accomplishes the need. So far, the only interfaces I've found are over $600 which is way too steep for my budget. Recommendations appreciated.

Thanks guys. I'm brand new to beams and rotor interfaces, so ANY assistance would be great. Private eMail is fine also as I'm sure I'll have other questions if you don't mind.

Chuck K.

25 amp switching powersupply . Any kind of 40 meter at all above 3
watts causes the ciricutry in the pwr supply to lose timing
cycle and shut off . Going back to a Transformer Based pwr supply .
full 100 watts both radios , and full 100 watts CW both radios on
to a common fed 4 band dipole (300 ohm twin lead) and mfj-949c
tuner.
>
>

The power supply is an Astron RS20A 20amp regulated power supply. I
don't think it is a switching power supply. It doesn't just happen
on 40, it happens on 20 and 17, the other two bands I've tried.

I know the power supply is also a possibility. I've ordered a dummy
load, something I should have already had but didn't, to see if the
problem is indeed RF related. I've replaced the power cable already
and the problem persists. The power supply is 13 years old, but it
hasn't been used much in the last several years because of poor band
conditions and my lack of an antenna for the lower bands.

I've been able to work CW ok which I enjoy, but phone is where most
of the trouble is.

Thanks for responding.

Stewart,

Great news.

Only difference is that this'll be canal water (it's a narrowboat) and other than a less efficient RF ground than sea water, the same practically.

Yes?

Callmu.

This may not help at all, but -- think about it.

In your house you have plumbing vents -- these are PVC pipes that tie to the drains and run through the roof. Their purpose is to provide atmospheric pressure on water running down the drain.

Climb up into your attic and check out the vent pipes -- they come from deep down inside the house and stick up through the roof. The roof doesn't leak where the pipes exit because the roofers put a "boot" around the pipe and shingle over and around the boot.

I am building a new house and this is what I am doing:
-- I got a piece of "black pipe" -- it's old-fashioned galvanized pipe with heavy black paint on it -- used for gas pipe, won't rust.
-- Threaded both ends. Put a floor flange on one end.
-- Across four ceiling joists, put a 2X8. Screw the floor flange onto the 2X8.
-- Cut a hole in the roof same size as the black pipe.
-- Stick the black pipe through the hole, screw it into the flange, U-bolt the black pipe onto a rafter (make certain the pipe is plumb).
-- put a boot around the black pipe and shingle the roof.
-- Screw a cap onto the black pipe to keep rain from running down it.
-- Now -- you have a piece of black pipe sticking out of the roof -- it's not going to move or bend. Make it as long as you like.
-- Secure one end of a wire antenna to the black pipe. Makes a great tie point for an inverted-Vee.

If you are going to use a metal mast that is built into the interior structure of your house, such as you described, I would give some though to lightning strikes and grounding. If that pipe is anywhere near any plumbing, or HVAC, or electrical wiring you can get an explosive arc from that mast. Even without the arc, do you want to attract lightning right into the frame of your house? I know any antenna will do that, certainly, but most of us take some kind of precautions along the way. Just a thought.

Date: 2008-02-09 17:29:00 UTC
From: aa5wg
Topic: 4035 Message: 4035

Hi to all:
Is there an advantage by placing the link input capacitor on the input side of link coil or on the output side of link coil? I have seen it drawn both ways, i.e. W6SAI handbook (input) and ARRL Antenna Handbook (output).
Does anyone have any experiece with this?
Thank you.
Chuck - AA5WG

I would put mine on the part after the coil to ground. I use to have a swinging link tuner. The Capacitor makes it most adjustable.

From: Callum M0MCX
Topic: 4034 Message: 4037

Why go half-wave when you can do this with quarter waves? Yes, I have experience of building such a little beast and damned excellent it was too - and cost very little.

See: http://www.m0mcx.co.uk/?p=68

Try it using MMANA? I may do this later for laughs.

Good luck,

Callum.

4039. 40 Meter NVIS Dipole Question

Yahoo group: ham-antennas (2008)
Date: 2008-02-09 19:26:59 UTC
From: Bill
Topic: 4039 Message: 4039

Hello everyone,
I was wondering if anyone could answer a couple of questions for me ?

I have put up a 40 Meter Horizontal dipole 7 Feet off the ground (I am playing with the NVIS antenna until I put it up higher or I might leave it and make another Dipole to put up Higher). I have the Dipole strung up from East to West. Now it seems to do very good at hearing signals that my 246 foot End fed random long wire antenna cannot hear.
(This antenna was originally 230 feet, then 229 feet, and now 246 feet. It tunes very well all HF Bands. Top band 160 was giving me trouble but alls good now with the versa tuner 2) I even talked to Cuba on 20 meters with it (maybe just conditions, Cuba was louder on the long wire, but contact was made with the Low NVIS dipole. I had to know...lol)). Not bad for only 7 feet off the ground I thought.... Each side of my low dipole is 33 feet...Not quite enough wire for 80 meters. It'll tune and hear but only half as good as the End fed random long wire. Not enough wire for 80 I recon...Now I am wondering if I could run 2 more wires each 33 feet in length North to south and connect to the other wires of the east to west dipole (kind of a fan dipole of sorts, but not really). The south 33 foot wire will not be able to go directly south it will have to go more of a southeast due to overhead powerlines. and the north 33 feet of wire will go directly North....
Will this work ? Will it maybe do better on 80 meters since each half of the dipole will have 66 feet of wire per side ??? If this works out I will probabily leave this antenna as a NVIS at 7 feet off the ground. I do want to get a resonant dipole up in the air for 40 meters. But this NVIS low antenna has heard alot of stations that would otherwise be lost in the noise. I was very suprised by the results of the low NVIS dipole....I am still new at building these kinda wire antennas. But one thing I have learned for sure. It's nice to have different antennas to switch to for the different band conditions...Very nice indeed...

If I hung the low NVIS Dipole like I described above would the antenna work like 2 seperate dipoles. one east to west and one north to south or would it be a whole different pattern all together. I know being NVIS that most of the signal is going straight. But to work Cuba (I'm near Dayton, Ohio) it must also still have some dipole patern going on...Am I correct in this assumption ???
Like I said above. I'm still kinda knew to building these wire antennas. Any help and other input would be much appreceated....

Thanks everyone...

73's...kc8ilp.....
http://www.kc8ilp.bravehost.com/

I was building this 40 meter dipole to put up high and I had it strung up low to see if there was gonna be any stretch factor in the wire. Then I decided since it is low maybe try the NVIS antenna out...Glad I did. I was very suprised by my results...Thanks everyone.....

Got to get these wire antennas built and up before the weather gets warm and nice...Hi Hi....

That was in 1970. It showed it that way in the handbook. The link is tuned to ground by the capacitor. I have never seen it any other way in a book. If you have many old radio handbooks you can trace development of the link capacitor from the time when it wasn't in the handbook and the link was adjusted by moving it in and out of the coil[swinging link]. Then it is noted in the handbook as a way to adjust the coupling[likely from QST] and then shown there after in the handbook. I use to have a lot of handbooks going back to 1946 . The link cap showed up in the early 1950's.

From: Wayne
Topic: 4034 Message: 4041

First, please turn off your cap locks key, makes it look like you are
either shouting or on a VIc 20 or Apple][+ with no shift mod.

Now, adding a director or reflector should not cause much, if any,
difference in the SWR of a dipole.
Matter of fact, the 2 meter beam that came to me taken apart and in a box
was put back together one element at a time, and I checked the SWR after
each step.
Now, if the SWR is high as a plain dipole, then a hairpin matching device
could help.
I have a tape measure beam, made with PVC and tape measure elements that
uses a hairpin match, and it does quite well. With a metal boom, it would
need some changes. Was made for fox hunting and portability, as the
elements can be rolled up when not in use.

The only way a director or reflector would change your SWR much might be
if you put them too close to the dipole (driven element).

I love playing with antennas...

4044. G5RV's good performance and high VSWR with tuned by a tuner

Yahoo group: ham-antennas (2008)
Date: 2008-02-10 08:01:03 UTC
From: xperts88
Topic: 4044 Message: 4044

Hi, I am Tim a newbee learned a few articles of G5RV and made it for 102' with 31'450 ohm ladder line with MFJ993B or MFJ962, bare foot using IC706MKII. Pleaee let me know this antenna really work well even on 80 75m band with auto or manual tuner though, I don't understand some 15m 17m 30m band is very high VSWR with the tuners.
I believe G5RV works very nice to DX and NVIS from low band to high band operation even in high SWR (4:1 or higher). I use 8 turns RG58AU for balun near the tuner. I would like to know whether this antenna is compromized multiband antenna or not and the relationship between high VSWR and good performance. I wish every band lower the VSWR. Tim AH2E

From: steve95446
Topic: 4044 Message: 4046

Hi, if it works for you stick with it. However, the G5RV is a compromise on 30m and 15m where the SWR is very high.

I have used a G5RV for JOTA for many years and it worked quite well. But I recently put one up as an inverted V as a test against dedicated dipoles and the results showed:

80m - about as good as the dipole on NVIS contacts around the UK.
40m - about the same again
20m - down 1-2 S points on the dipole
15m - down 2-4 S S points on the dipole

No tests were done on 12 and 10m.

Best bet with a G5RV is continue the twin feeder to the ATU and treat it as Windom, Otherwise, losses will be high on the coax on those bands with poor SWR.

Steve G0KYA

4047. Re: Reflector or director with vetricle

Yahoo group: ham-antennas (2008)

From: john_tartar
Topic: 4045 Message: 4047

Adding a reflector to and antenna, if properly tuned for gian, greatly reduces the feedpoint impedance. Most good beams have hairpin match to trnsform the low impedance up to 50ohms.

In theory one could add parasitic elements to a vertical, but the feedpoint impedance would be lowered, and ground losses would increse.

For example the thoeretical impedance of a 1/4 wave vertical is 35 ohms. Most hams end up matching these to 50 ohms directly because there is 15 ohms of ground loss. About 1/3 of your transmit power is being lost to the ground, but thats no too bad. Now if you ad a reflector, the feed point impendances drops down to ~5 ohms. If you still have 15 ohms of grond loss, then 3/4 of your power is being lost into ground.

Now the original idea, of adding reflectors to a 1/2 wave vertical is an excellent one. Especially if it is a 1/2 wave end fed antenna, where the impedance is very high, and the ground losses are insignificant.

If you add a single vertical parasictic element, in should be ungrounded (floating) and tuned about 5% below the operating frequency for a reflector, or 5% above the operating frequency and it for a director. You can also use a small center loading coil to adjust the resonance. So with a switched loading coil you can change the parasitic elements performance form a reflector to a director, thus reversing the direction of the antenna.

The G5RV is a compromise. A dipole fed with ladder line should perform better.

Thanks for your report. Excellent job...

From: Callum M0MCX
Topic: 4049 Message: 4049

Some of you know that I am very close to having to make my mind up over this damned vertical system for a 70 foot steel boat that□s being made.

On the one hand, I am thinking of going down an ATU route such as the SG-230 (actually, the high-power version or a copy of; SG-235) and a 28 foot vertical for general purpose HF work.

On the other hand, for about the same money, I could buy a BigIr from Steppir that covers 80m through to 6m (and it would handle substantially more power) but looks a bit crappy.

Now, I was originally taught that a 5/8 wave (for instance) had a better DX radiation pattern than a ¼ wave however doing some modelling this afternoon, it transpires that a □random□ 8.5 meter length of marine vertical will kick out some not-so-perfect patterns of RF at the higher frequencies.

So I□m slightly confused. Which is better?

Callum.

I just slapped a hamfest quality G5RV in my trees recently and did exactly that, cut the balun off and extended the window line right into the shack and my Palstar tuner.

Much better performance, though anectdotal , signal reports on regular nets have been better than they were. Electrically, I'm sure that I'm putting much more signal on the wire vs coax and a balun for wide band use.

I can get mine loaded up on 160 and 75 just fine, though at 160 I could probably make toast on the tuner more efficiently than I'm radiating, but I make regional contacts with good reports anyway.

The curious part is how much more noise I get on my wire vs my vertical. It's a lot more noisy at least at this QTH than the vertical...then again, it receives much better too. Always interesting playing with antennas, that's the one sure thing in the whole game.

Hello Callum: My 2 cents worth, the big commercial manufactures of commercial radio equipment especially McKay, Trans world and Harris all use antenna couplers at the antenna and drive a 35 foot mast for most of the marine communication. This has been a tried and proven method for quite some time now. Now you can look at this 2 ways, either they think this is a prefer ed method for marine use , or they want to sell antenna couplers and this is the way to do it. For a fixed base station using a coupler at the antenna base seems to work quite well for me, but I am not out in a boat either. Just a point a view without re inventing the wheel. Frank

I am sure this will be a bit controversial, But it would seem that thru the many, many books and actual demonstrations I have seen. Your "8 turns RG58AU for balun" should be as near the feed point of the antenna as possible. In your case you want your balun to be directly below your coax to ladder line transition. doing this will keep the RF from traveling down the braid to your tuner. What you have now is all that reflected rf is going back to your tuner instead of toward the antenna. The other thing I would mention is to possibly increase your turns when you move the balun to 10 turns @ minimum 6" diameter. Also note that you should not just scramble wind the turns. if you scramble wind, the turns will cancel out and you may only be seeing electrically 2 or 3 turns. Nice neat side by side close spaced turns will allow you to see the full potential of the coil.

Here is a homebrew page with some text and many fotos showing many different coaxial baluns in use in a variety of different antenna configurations.

http://www.hamuniverse.com/balun.html<http://www.hamuniverse.com/balun.html>

Another very in depth site to go to that is a must read in my opinion:

http://www.cebik.com/wire/g5rv2.html<http://www.cebik.com/wire/g5rv2.html>

Cebik has posted many pages on a wide variety of antenna types and is an excellent resource.

Subject: [ham-antennas] G5RV's good performance and high VSWR with tuned by a tuner

Hi, I am Tim a newbee learned a few articles of G5RV and made it for 102' with 31'450 ohm ladder line with MFJ993B or MFJ962, bare foot using IC706MKII. Pleaee let me know this antenna really work well even on 80 75m band with auto or manual tuner though, I don't understand some 15m 17m 30m band is very high VSWR with the tuners.
I believe G5RV works very nice to DX and NVIS from low band to high band operation even in high SWR (4:1 or higher). I use 8 turns RG58AU for balun near the tuner. I would like to know whether this antenna is compromized multiband antenna or not and the relationship between high VSWR and good performance. I wish every band lower the VSWR. Tim AH2E

I've been thinking of doing the same thing, except for running a 3 ft piece of coax from the ladder line through the window to the rig. What do you guys think of that?

Gang,
If you have the room, get the Van Gorden All Bander. Its 135' long and fed in the center with 100' of 450 ohm line and only costs about 40 bucks - hard to buy the parts for that much to build it yourself ! I think AES and Universal Radio carries them, but with the right tuner they will cover 10 thru 160 meters !

Karl

I have been using a 102 ft G5RV as an inverted V mounted 28 ft up at the apex. It has the Balun between twin lead and coax to shack. Coax is maybe 12 ft long. I have worked 114 countries on 75/80 and 24 countries on 60 meters since mid Sept. I use an MFJ Versa Tuner with rotary inductor. Works great for me. Actually, I added 2.5 ft to each end so that it tunes more easily at the DX Windows on 80 CW and 75 SSB. I get a 1.1:1 SWR with the tuner.

Best Regards
Dan Schaaf

Callum,
A friend of mine has great success using a 31 foot (10M) telescopic fiberglas pole from www.jackite.com with a same length of #14 wire ran through the center of it and fed with an Icom AH-4 autotuner for 10 thru 80 meter coverage. He uses it on his aluminum pontoon boat and gets good reports from all over. His ground is simply the aluminum hull of the boat.

Should work fine, but make a coaxial choke right where the coax connects to the balanced feedline to help keep RF from flowing on the outside of the coax shield. Another way is to slip several ferrite beads over the coax.

Thanks Frank and Rick, good input.

Another source has just explained that he□d prefer a ¼ wave for every frequency since we□re not like marine frequency guys, we hop right up to the 10 m band (and beyond).

I do realise that for genuine marine bands, mostly the 8.5 meter (28 foot) whip would work exceptionally well for lots of their 8Mhz work and the middle to lower HF bands □ I am only getting concerned because much of our DX is above 14 Mhz when the rf bubble that these longer whips generate starts to go a bit cock-eyed (pancake with a high NVIS component).

C.

You could try a extendable fiberglass painters pole, they come in some
pretty good lengths. I think i had one that extended to about 12 feet
or so. Hope this helps

I.ve put up a couple of these over the years. What is critical
is dressing the twinlead away from the flattop at a 90 degree
angle and getting it just the right length (or routing it
directly to a good tuner without using a coax length. Properly
installed and tuned it works. I had a QSO with Lou back in the
late 1970's from VE1EI in suburban Halifax and he had a
respectable (though not outstanding) signal on my vertical array.
Dale (VE7GL now) was putting up a large twin sloper delta
reflector array for a G2 ham and was party to that same QSO. The
big antenna was giving me clearly much sharper audio and several
S units better signal, but consider the difference!

I replaced sked 80 x20 ft pipe with a extruded Aluminum 1/2 " wall 24 ft
it was so flexible it was to scary to install so I found a lumber store
that had Maple Banister rail in 3 ft section for sale .
Now being this was wood working and not metal turning the size was
with in a wide tolerance so I brought my Machinist Caliper with me to
get the fit right.

I pounded the wood into the mast and never looked back when the
worst storm I have ever been in came through town 5 yrs later touched
down for about one mile ripping up a lot of stuff taking a huge tree limb
tossing it at the tower like a laser guided missile putting the tower and
antennas into the roof next store the mast survived but I lost all the
antennas
which you can see at ka9zap.com I know Aluminum is not right
for mast but this one lived to play another day I did cut it with a saw for
fast disassembly and am reusing the longest piece now
You can see the before and after at ka9zap.com
Regards
Art

There are some extendable poles that go to maybe 18 feet, give or take.
But less than 1" diamter may be a tough row to hoe, as they used to say.
I don't think that 1/2" Schedule 80 would be as stiff as one would really
want, especially if you get winds at times.
YMMV

4069. My Recent PAC-12 Outing

Yahoo group: ham-antennas (2008)
Date: 2008-02-11 20:58:18 UTC
From: Mark, KJ7BS
Topic: 4069 Message: 4069

Wow! What a time I had.

I managed to push up my plans by one day and start portable operations on Saturday. Operations on Saturday and Sunday were impressive.

I have only used my PAC-12 antenna with coils for individual bands and was not overly impressed. That is to say, the PAC-12 performed as expected on the 3 bands I have, 20, 30, and 40 meters requiring me to break down the antenna to change bands. Inconvenient at best.

Enter the 10-40 meter adjustable coil with tap. I had this coil built for almost a year but never had an opportunity to properly test it. Using my MFJ-259B, I found points close to resonate (SWR 2:1 or less) and marked it for each band. In the field my Elecraft K2's internal auto tuner takes care of this slight mismatch while the LDG RT-11 I use with my ICOM IC-706MKIIG handles the mismatch in this combination. Actually using the 10-40 meter coil was a breeze. Simply unclip the tap from the coil and attach it to the location on the coil corresponding to the band selected, push the tune button on the radio and BINGO, all set to operate.

Field report? Some of the reasons I pushed up my plans were (1) the FISTS Winter Sprint on Saturday, (2) the SKCC Junkbox Warz Saturday and Sunday. I thought these would offer better opportunities for contacts and give better coverage to compare performance.

Let me digress and say a little about FISTS and SKCC. FISTS is the International Morse Preservation Society with thousands of members worldwide who enjoy Morse code. You can find more information at http://www.fists.org . Their Winter Sprint was held this past weekend and is a blast to operate and is highly competitive. SKCC is the Straight Key Century Club with just over 4000 members worldwide who are dedicated to manually generated Morse code (straight keys, bugs, cooties, sideswipers), but nothing automated by electronic keyers or keyboards. More information on SKCC is available at http://www.skccgroup.com . Their Junkbox Warz requires participants to build a keying device from their junkbox without using power tools and then operate the contest with it. What a kick. If you enjoy CW, please check into these clubs.

Now back to our regularly scheduled message. . .

In the two days of portable operations I made 43 contacts and changed operating locations 3 different times (rest stop 45 miles South of Flagstaff, AZ on I-17, Stoneman Lake road about 30 miles South of Flagstaff , AZ about 1 mile east of I-17 in about a foot of snow, and the Snow Bowl ski resort about 10 miles Northwest of Flagstaff, AZ in about 50 inches of snow.

I made several FISTS and SKCC contacts, but I did not expect to make Japan, Brazil, or Argentina. Those were a surprise working off a portable antenna.

PAC-12 Antenna - http://www.pacificantenna.com/

I am in no way associated with Pacific Antennas, simply an happy user of a PAC-12 antenna.

The two section pole my brother found some time back was green if I rcall correctly.
And I have a pole pruner here, sections about 6 foot or so, and green.
try places that sell major gardening tools and such.
Worst case, you could paint it or tape over it.
I'd be careful using some types of paint, as they might damage the material the poles are made of.
If the pole is fiberglas, they do make a paint for the material, or one could use resin top coat with added color.
Someone once suggested painting an antenna mast sky blue so it would be less noticed.

From: pitbon
Topic: 4071 Message: 4071

Ok I am a real nOoB at this antenna building but I have installed a G5RV jr on my roof with the balun at approx.27-30 feet high. The length of my G5RV jr. is 51 foot long and my roof is shorter than this and here is my question... I cant raise the antenna any higher due to HOA so i turned the ends at 90 degree angleto accomodate my roof length, how else can i do this for better performance and feep it low profile for my HOA?

Here is a link to the picture ...G5RV jr
<http://i19.photobucket.com/albums/b151/bondo66/HAM/101_0161.jpg> ...
The vertical is a 2 meter that operates supremely!

ANY suggestions will be appreciated greatly!

Thanks in advance!

Bonner, KJ4BKK

Bonner

What are the HOA height restrictions?

What bands do you want to work?

Best Regards

Hi Chiris,
Thanks for your reply and I would like to ask soemthing.
How long do you extended line about? and just ask about your
Palstar model # like ATR30?
How much power do you put into your G5RV as you made a choice to use
just twin feeder without no balun?
73 OM Tim,

> I just slapped a hamfest quality G5RV in my trees recently and did

Hi Rick,
Just for reference, Does the only 135' long Vag Golden All Bander
cover 80,75m or even 160m band to 10m with 100' 450 ohm line?
Though I could have a restircted space in the island, I could draw
30-50ft twin lead into some cottage. Do you recoommend another one?
73 Tim,

> Gang,
> If you have the room, get the Van Gorden All Bander. Its 135'
long and
> fed in the center with 100' of 450 ohm line and only costs about 40
bucks

Hi Dan,
Your opinion is very helpful for me I have been looking for.
I would like to ask something as below.
Your antenna installation is close to mine.
I have some MFJ manual tuners 962D and other auto tuner like 993B
SGC 230 239 for 160m to 6m for portable use.
Do you think better the balun between twin feeder to coax cable to TRX?
Do you think the 2.5ft of 450 feeder is effective to some smaller
tuners or auto tuners?
73 Tim,

> I have been using a 102 ft G5RV as an inverted V mounted 28 ft up at
the apex. It has the Balun between twin lead and coax to shack. Coax
is maybe 12 ft long. I have worked 114 countries on 75/80 and 24
countries on 60 meters since mid Sept. I use an MFJ Versa Tuner with
rotary inductor. Works great for me. Actually, I added 2.5 ft to each
end so that it tunes more easily at the DX Windows on 80 CW and 75
SSB. I get a 1.1:1 SWR with the tuner.

From: aadu.adok
Topic: 4078 Message: 4078

hello,

I have a small lot (100 x 100 feet). I would like to put up dx-able antenna for 40m (waiting for better solar activity for higher band antennas). because of neighbors I'm not considering 2 element yagi nor multi el quad. So currently I'm thinking about:

* vertical
* delta loop
* g5rv

I would really appreciate if someone would comment those 3 antennas. Is it realistic to work dx from europe with any of them?

thanks a lot!!

4079. RE: [ham-antennas] dx antenna for 40m

From: Callum M0MCX
Topic: 4078 Message: 4079

Hello NoName

Go vertical if you want to have a bit of DX fun on 40m; see
http://www.m0mcx.co.uk/?p=68

You have enough space for a 4-square which would blow the pants off
everything you list.

C.

Hi again,

If you model the G5RV with a program like MMANA or EZNEC you will find that it shows a very high SWR on 30m and 15m. In fact, on the one I tried it had a high SWR on other bands too.

If you use a coax loss calculator you will see that high SWR and coax is not a good mix - 40 feet of coax and a 12:1 SWR equals half of your power heating up the coax (3db loss).

Much better to use open wire feeder which has neglible loss at HF. The slotted 300Ohm type will easily pass around window frames.

The G5RV works well on 80 amd 40 in terms of NVIS, round the UK, contacts. It is down a couple of S points compared with a half wave dipole on 20m. High reactances mean that it can also create high voltages in your ATU on 10m too.

Having said that, it is dirt cheap.

Take a look at LB Cebik's site on the net and/or any of the excellent ARRL antenna books or the RSGB's "Backyard antennas".

A G5RV IS a dipole. There is an argument made that with some setups, and with some frequencies, there is a vertical component to it. But there are MUCH better ways to get the pattern you would want and need for a vertical component with other antennas. Ladder line, by nature, has less loss than coax, especially when the antenna is not matched, and a G5RV by design has a higher SWR, and it is very bad on some of its frequencies. If designed properly, you may see a 2:1 on some bands with a G5RV, which is acceptable for older tube rigs, but not so good with newer solid state rigs, so therefore, you need a tuner with a G5RV.

So IF you are going to have an higher SWR, as an inherent part of the antenna and design, you might as well go with a longer dipole with using ladder line. Ladder line has less loss. So, with an antenna tuner being used, which you will need for a G5RV with the newer rigs, then there is no benefit to going with a G5RV. Do the math... Don't listen to the hype. Do the math...

But if you really want to rid yourself of coaxial losses, place your tuner at the antenna feed point OR match all your antennas so that you do not need a tuner (fan dipole is cool). But going without a tuner is a thing of the past, perhaps. A G5RV is a compromise and was designed for older tube rigs out of convenience. It has survived through marketing and hype, not through science.

I use an AH-4 and it tunes at the antenna feed point, allowing for much, much less loss in the coax.

Hello Garth,
Thank you very much for excellent advice.
For reference, I don't have ARRL Antenna Book for example,though I
want it but it is very expensive for me.
I have some similar questions to other amateurs though, I would like
to ask you. As local dwellers banned the antenna installation at the
roof top.So G5RV half is better for me. I would use ladder line but
drawing it, it is still longer to any windows so I would like to fold
back ,closely ovelap and bind them. and it is better to use light weight
legal limit balun. Could I fold back some feet above and alter the
coaxial cable balun to some firm made KW balun?
On the other hand I will make the 10 turns @ minimum 6" diameter coax
balun. Could this coax out on the the same field as externalautomatic
tuner with some radials?
If I made your coax balun, how long should I draw coax cable into the
room to coax balun? The shorter, the better?
73 Tim AH2E

Figured I'd follow up on this since I've now had a bunch of time
operating with the changed setup.

On 160m I load up fine and it works for regional, but full national,
it just isn't high enough up to work well, it's too NVIS oriented.
The top of it is probably only 35 feet.

80m works very well for regional as well, very happy there with it.

40m is solid

20m is solid, probably the best band for the antenna, which follows the math.

I can get 17m , 15m, 12m tuned, but run out of string on the tuner for
10m. My vertical works so well on these bands though that I generally
just use it there anyway.

Subject: [ham-antennas] Re: G5RV's good performance and high VSWR with tuned by a tuner

Hi Steve again,
I would like to ask you something.
What do you mean the a dipole fee with ladder line should perform better? Do you recommended other multiband one?
When using G5RV,
Which is better drawing the ladder line through window flame or a long coaxial cable connected in series through the window.
Well do you recommend some essential books for me?
73 Tim,

Good deal and good point.

But in reality, when you look at how these perform using a modeling program, there ain't a whole lot of difference.

HI, Dave
Thanks for your reply.
A friend in Halifax now moved to Tronto,--- I am envy yoour big antennas
and their arrays I've never try some or will never try any in the
island area hi.
Well do you show me the book or URL of your great vertical array
and how to make with photos and twin sloper Delta reflector array.
I am interested to look at anywhere.
73 Tim,

Hi Chris,
I am appreciated to learn your figured and actual data.
On 160m and 80m 75m band, could you install the element formed inverted V or holizontally?
I know the height of apex is 34ft of 160m G5RV very enough to intercontinental QSOs.
I will try verticals then ask something here...
How do you think about baluns in serious of ladder line?
73 Tim. AH2E

Hi again,
Thanks for your reply.
I understand much more about this antenna and a history of its use.
As I have few space, So I have been used Outbacker or other mobile
whip with full length radials but bent stealthy. But I could not get a
fair ground, the other half element didn't work well for decades.
Then I have been thinking about using ladder line and wire length
and did a math to operate in lots of band, but both my holizontal
space for dipole element is restricted and vertical space as well.
So I still need a compromized but effective radiation as possible and
have been looking for.This is based on my 30 years experience.
So what I need is an antenna for portable use by my vehicle and also
use it in my shack.
You recommend "a fan dipole " as
http://www.hamuniverse.com/multidipole.html
I tried his but there is not enough space to install then bend every
elements so some elements release and pull ropes then VSWR got worse
because of closed to some materials or a wall.
Cobra Jr. I made is very heavy.
So to bend ladder line itself and bind them tightly, not form cirlce
Does this way make a few effect or large effect as RF line?
Best regards,
Tim

> But if you really want to rid yourself of coaxial losses, place your
tuner at the antenna feed point OR match all your antennas so that you
do not need a tuner (fan dipole is cool). But going without a tuner
is a thing of the past, perhaps. A G5RV is a compromise and was
designed for older tube rigs out of convenience. It has survived
through marketing and hype, not through science.
>
> I use an AH-4 and it tunes at the antenna feed point, allowing for
much, much less loss in the coax.
>
> W8OKN

4098. Alpha Delta DX-EE Performance

Yahoo group: ham-antennas (2008)
Date: 2008-02-12 23:20:30 UTC
From: Jon Maguire
Topic: 4098 Message: 4098

I have one of the subject antennas that I plan on putting up with the apex at approx. 20 feet. Does anyone have any experience with this antenna? I realize that it is a compromise, but with an HOA and arthritis to deal with, I thought I would give it a try. I want to use it for 30M and 40M, as my R5 vertical is very "challenged" on those bamds. I also have 2 MFJ antenna tuners and will run 100 watts. 600 to 1000 watts are also a possibility, but unlikely. QRP looks better and better every day. Any comments are greatly appreciated.

Do a search of F.B. Cebik. He has written volumes about all kinds of antenna's, also ARRL Handbook and Antenna Anthology.

Have you considered a multi-element Quad? Easy to build, High gain, and If interested I have plans, and could provide pictures.

It is not resonant on 30M and Bandwidth is limited on 40M but with a tuner you should be able to use it pretty well. Remember to put the arc capsule or it will short out from high SWR on 30M.

I use the big brother, DX-CC with good luck on 80/40/20/15. Haven't done much more than check the SWR on 30 and it was rather high.

I'm wanting to construct a 2m 1/2 wave and a fullwave base antennas.
[snip]

Is there a reason you want 1/2 wave and full wave antennas ? Quarter wave antennas are much easier to build, but the Jpole antenna is a halfwave antenna with a quarter wave matching section - I have the plans for one on my website to which there is a link in my signature below. Once you get to the main site, look around in the links to my various projects for the Jpole and click on it. I have built several of these and they work as well or better than commercial antennas. They also are very broadbanded with a low swr on the entire 2 meter band. They are made from ordinary hardware store 1/2 inch copper tubing.

Just for reference, Does the only 135' long Vag Golden All Bander cover 80,75m or even 160m band to 10m with 100' 450 ohm line? [snip]

Tim & Gang,
The Van Gordon All Bander is an old classic antenna that covers "ALL BANDS" 10 thru 80 meters but must use a tuner. With some tuners it will even cover 160 meters but is somewhat of a compromise on that band. So to answer your question, yes it does cover 75 & 80 meters and can possibly cover 160 with the right tuner. At one time I used a homebrew version of it here with great success but finally took it down to put up a bigger antenna. Now I use a 40 meter extended double zepp that is a 179' centerfed doublet and it covers 10 thru 160 meters just fine. But for the money (around $39) the Van Gordon All Bander is mighty hard to beat - I don't think you could buy the materials ad build it yourself for that kind of money seeing the price of copper wire these days ! If you can't find the Van Gordon All Bander though, you can always build your own. You will need 135' of #14 stranded copper wire (I prefer insulated wire), 3 insulators, and whatever length of 450 ohm balanced feedline you need to reach from the antenna feedpoint to the shack. Take the 135' wire and fold it in half to mark the center, then cut it in two at that point. Tie each half to the center insulator, and tie an insulator to the far ends of each half, then attach the feedline to each half at the center insulator. Hang it up as high as you can get it, and you can even hang it with the center supported and the ends hanging lower like an inverted V and run the feedline to the shack to the tuner. If all you can put up is one antenna, this one will serve you well without spending bunches of money.

I have a small lot (100 x 100 feet). I would like to put up dx-able antenna for 40m [snip]

Put up a simple 1/4 wave vertical for 40 meters with several ground radials - I've worked lots of DX with such an arrangement. Even worked my best DX yet on 40 meters with 10 watts SSB - Australia, which is about 10,000 miles away from here !

Also, you can use basicall the same antenna for all bands with the addition of an auto tuner at the base of the vertical. A friend of mine uses a 31' telescopic fiberglas pole with a 31' #14 wire ran up through the inside of it and connected the base of the wire to an Icom AH-4 tuner and gets 10 thru 80 meter coverage with it. To make the vertical, you could also use aluminum tubing but the fiberglas pole and wire works mighty fine for him and he works a lot of DX with it on 40 !

howdy,

I have been reading lots of good reviews about 1/4 verticals for 40m. HF2V seems a good choice. Now I have few questions about vertical installation.

This is how I'm thinking about it: I'll take 4 feet long 2 inch aluminium tube (let's call it an anchor tube). Then I'll dig a 3 foot deep hole into ground and secure anchor tube with concrete. 1 feet of anchor tube will be above the ground. Two inches below ground level (connected with saddle around the anchor tube) will come DX-engineering radial plate (http://www.dxengineering.com/Products.asp?ID=47&SecID=109&DeptID=32). At least 60 30' radials will be connected to radial plate. I'll put radials initially on the ground and cover them with 2 inch thick soil layer (I was planning to bring new soil and plant new lawn anyway). So - now the anchor tube should be rock solid (due to concrete under ground), very well radial connected, and only 1 feet of it should be visible above the ground. Okay.. Now I will connect solid aluminium rectangle shaped plate to my anchor with 3 u-bolts. My HF2V will be connected to the same plate with another 3 u-bolts.

Everything should be fine and dandy, and I should be able to use my lawn-mower around the antenna (and forget about the radials below the ground).

My concerns (and questions) are: wont the radial plate connections corrode under ground? Will the connection of antenna to anchor tube via rectangular plate and u-bolts be solid enough (I mean electrically, not mechanically)? And finally - I would like to put the coaxial running from antenna to the shack also under ground. So I guess my coaxial should come from the ground right next to anchor tube. Coaxial shield should be connected to anchor tube with screw. But how should I connect the inner thread of coaxial?

Sorry for the long story, but I really like to get it right at the first time ;)

> I am interested to look at anywhere.

I'm off HF altogether these days (except to listen) due to RFI
and an apartment QTH. I don't have any pictures of my verticals.
They were Electrospace verticals, with about a six foot capacity
hat at the top and a triband tuning unit at the base, fed with
equal lengths of RG8X. I made a phasing box with chunks of
coiled coax in it and switches to change the amount of delay and
which antenna's feed was delayed. The SWR was about 2 but my
FL2100B loaded into it just fine, even without a tuner.

The trick was to put 16 antenna-length radials under each
vertical.

Hello group,

Thanks to all for the suggestions, hyperlinks and pictures. I hadn't thought of a J-pole but I'm thinking about it now! I'm in the process of constructing both 1/2 wave and fullwave verticals with 1/4 ground radials. Are there any electrical or theoretical reasons why these won't work? Or is there a coil, balun or somethings else that needs to be added to make them work? Being a Noob there's lot's I don't know or even where to look for the answers.

Cheers!

The half wave and full wave verticals have the same issues with feed point. If you try and end feed them the impedence is very high. That is the reason the J-pole uses a 1/4 wave matching section to bring the impedance down. You could easily extend the 1/2 wave section of the jpole to make a full wave section. If you decide to go some other way with and end fed you will need to design a matching section.

An alternative you can use with the 1/2 wave is to center feed it. Then you have a standard dipole configuration. For the 1/2 wave you would just add 1/2 wave to one end of your dipole to make it off center fed.

Now you may want to do some research on the pattern of a full wave radiator. If I remember correctly it doesn't have a single large lobe like the 1/2 wave but instead has more of leaf pattern with 4 lobes.

Hi Rick again,
Thank you for your lots ofhomebrew antenna information here.
If you can recommend some tuner for 160m band match for portable
use.a big tuner with LC or Pai match unit with a math or buy some
tuner may be needed though.
And you are very good DEZ antenna and have a wide field.
The other question is how to drag the 100ft laddar line that could not
touch any soil or any material?
CU 73 Tim,

hi doug,

take a look at the Moxon for 2m,

easy to build using aluminum rod 3/16" or
6 bare copper wire (or #10 etc)

Direct fed with 50 ohm coax, no matching needed
gain similar to a two element Yagi but takes up less space.
use it vertical for FM or horiziontal for SSB.

http://www.cebik.com/moxon/moxbld.html

or if you want to get on the air faster,
try the half square for 2m

http://www.cebik.com/vhf/hs.html

build it for a few dollars worth of pvc 1/2" pipe
and # 12 thhn solid wire, again direct fed 50 ohm coax.

both are directional antenna designs.

Doug,

Take a look at http://ph.groups.yahoo.com/group/ham-antennas/photos/browse/7179

Cost to build was approx $10 Measured gain (yes, I have access to a certified antenna range) was 3.2 dBd or 5.3 dBi.

Hello Tim,
Not sure what you really mean here, but just cut the ladder line just long enough to reach the shack - no need to keep it 100' on the all bander. So just cut it to whatever length you need to reach the tuner with a little extra to allow for rearranging the shack.

Bonner,

What is your antenna elevation in reference to the 150 mile stations?
Do you routinely talk on the repeaters that far away.

I am truly impressed that a J-Pole Omni can provide that performance,
while not unheard of.

I am moving farther away from the Austin TX repeaters this summer, but
not a huge margin, 50 miles out or so. The elevation of where I plan
to move is 200 ft or so reduced as to where I am in North Austin and
was considering a dual band beam application.

If the J-Pole performs that well and I can get it up high enough, I
will not consider a beam implementation the first round.

What are you using for feedline?

Thanks for sharing that!

Brian,

When you find the J-pole lacking, take a look at a Elk Log Periodic. I have one and love it. I can routinely reach high repeaters 100 miles away.

Just a quick note on 2 meter antennas. Odd multiples of a quarter wave are easier to match to 50 ohms, but multiples of halfwaves are high impedance (around 5000 ohms) and require some sort of matching network to match to a 50 ohm feedline such as the Jpole uses (quarter wave matching section) So, if you want to build a simple vertical for 2 meters that has a little gain, you could build a 3/4 wave ground plane with quarter wave ground radials. The 3/4 wave groundplane for 2 meters is about 58 inches tall with 20 inch radials that slope down at about a 45 degree angle. Incidently, a quarter wave antenna for 2 meters will also work as a 3/4 wave on 440 !

Hi Rick,

>> Incidently, a quarter wave antenna for 2 meters will also work as
a 3/4 wave on 440 !

I've just built a ¼ wave for 2m and as you say it gives a very good match on 70cm. Software modeling predicts about a 6dbi gain (10m over ground) on the ¼ wave for 2m at about 3 deg radiation angle, This seems to be the case in real world tests against previous antennas.

If anyone wants a small very effective homebrew 2m antenna the ¼ wave vertical is a very good option.

And very effective they seem to be too,

On a 100ft x 100ft plot you should be able to build a very good 40m vertical, the fiberglass pole is the easiest way, a 10 meter one costs about £26 in the UK (that's about $50) if you can get it on a pole with 4 elevated radials it will work very well for DX, this also works pretty well when hooked up to an auto tuner (SG-230) for 80m through to 10m. Or if an auto tuner is not an option feed it with 450ohm ladder line to a tuner in the shack.

I built one last weekend fed with open wire feeder (Approx 450ohm, it was homebrew feeder) from an SG-230, the garden at my QTH is not very wide so it only had 2 elevated radials, but it still seemed to work very well.

4128. How to deal G5RV's laddar line to coax cable through a balun

Yahoo group: ham-antennas (2008)
Date: 2008-02-14 01:30:10 UTC
From: xperts88
Topic: 4044 Message: 4128

Hello Gary,
I am happy to know you will get ALL BANDER soon.
Some OMs had advised me,
The vertical radiation is very important then the ladder line
if 10-80m band original G5RV should have 31'long with a balun and
pull them avoid scrawling near the house materials or drag on the
soils because both lines radiate to the air as well.
Do you understand what I want to ask now ?
73 Tim,

> The other question is how to drag the 100ft laddar line that could not

Hey Brian,

I'll investigate the elevation references because i am not sure there. My jpole is approx 25'-28' at its base and then it is 10' tall.I connected my coax directly to the antenna with approx. 30 feet to my radio. and as i said i get a 1:1 swr. I am pretty new to this also so there was no theory, i just built it as the plan suggested other than the wrapping the line at the bottom since i had the 1:1 swr.

How would i go about checking elevations by the way?

thanks!

From: Gary H. Harmon, Jr
Topic: 4044 Message: 4130

Hi Tim,

I think what they are saying is that it is not necessary to use all the ladder line that comes with the antenna. Just hang the puppy, route the ladder line in a reasonable manner, and cut off any extra you don't need.

If I have misread the previous answers please correct me now.

Hello Gary,
I am happy to know you will get ALL BANDER soon.
Some OMs had advised me,
The vertical radiation is very important then the ladder line
if 10-80m band original G5RV should have 31'long with a balun and
pull them avoid scrawling near the house materials or drag on the
soils because both lines radiate to the air as well.
Do you understand what I want to ask now ?
73 Tim,

I looked you up on Google Earth. Your elevation is 601 feet.

Nice pool and tennis court in your subdivision.

If you are planning on installing a G5RV that is 102 feet in total length then the 450 ohm ladder line length is important.
I use this antenna, and I have 31 feet of ladder line which is connected directly to the coax. no balun, no line isolator. I simply coiled the coax into a loop with approx. 10 turns of coax. No RF in the shack.
The ladder line comes down from the feed point and is suspended away from the tower roughly 2.5 feet all the way down the tower. It comes right down to the ground then joins the coax. I only have it suspended about 29 feet off the ground, so that is why the ladder line comes down right to the ground. However it never touches the ground or any metal. I also have vinyl siding on my home so that does not effect the ladder line.
The 31 feet is critical for this antenna to work properly.

If you are going to install an all band doublet for 80-10 then the total length would be 113 feet, which would cover 3.5-30 Mhz. In that case the experts say you need 100 feet of ladder line for the feed line. Now there lies the problem of what to do with 100 feet of ladder line if you only have a 50 foot tower! Do not coil that ladder line up, that just messes up the radiation pattern of the antenna. You can bring it down the tower, suspended away from the tower of course. Then extend it out away from the tower, off the ground and then bring it back to the shack. As long as the ladder line is off the ground, and high enough off the ground to not be bothered by dogs, children or snow then you are ok. Your tuner will need a good 4:1 balun or you can install a 4:1 balun at the end of the ladder line then run coax to the tuner. I have never used the above antenna but nearly ever article I have read during 16 years of being an Amateur has always called for 100 feet of ladder line for the doublet.

NO! The length of the ladder line is critical and must be 31 ft for a full sized G5RV. It's an active part of the antenna. You can roll it up, but don't cut it.

Yeah they are redoing the front of our clubhouse right now ...outside
that is, and yes it is very nice, it gets alot of use during the summer!

So 601! Now i wonder about the repeater?

Ok it is 104 miles as the bird flies and it is at an elevation of 698.

So does that tell you anything?

I am not up on all aspects of a full wave vertical ground plane, but know it does need some kind of match. the matching device could be a base coil with a tap, or possibly a hairpin match at the half or maybe 3/4 wave point.
There are plans online for J Poles of more than 1/2 wave design, and those use hairpin matching devices between the sections.
It can be tricky to make, and I tend to suggest using aluminum to keep the weight down, and make it easier. And a well treated dowel rod may be the best thing to use between the sections.
Copper is too heavy, and you want the antenna to be light, which means it stays together better in high winds, if constructed right.
I'll do some search later on, when I get enough time, and post some URL's for you to look at...

4136. 40m vertical radials

Yahoo group: ham-antennas (2008)
Date: 2008-02-14 09:19:32 UTC
From: aadu.adok
Topic: 4136 Message: 4136

hello,

does it make a big difference if the radials are evenly around the antenna (in the ground)?

I would like to put the antenna to the corner of my garden - so I have only 90 degrees for radials (other 270 degrees are neighbors territory).

Or should I move the antenna more to the center of my garden..say 10 feet from the corner? Even then I have to bend most of the radials.

Any thoughts please.

73,
Aadu

You really did not mean to say "you can roll it up", did you?
No, you can nor roll up ladder line and expect it to behave like a
transmission line. It will behave like a rolled up piece of wire.

NO! The length of the ladder line is critical and must be 31 ft for a full sized G5RV. It's an active part of the antenna. You can roll it up, but don't cut it.

Wasn't talking about a G5RV, we was talking about the Van Gordon All Bander that comes with 100' of feedline. But if I was using a G5RV, I would do away with the coax and extend the balanced feedline all the way to the shack for greater efficiency.

If you are willing to use window/ladder line right to your tuner.
Just go ahead and make the length 135' instead of using a 102' length.
It will give you much nicer efficiency on 75/80m and your tuner will
still be able to tune it all the way up.

I only modified a G5RV out of laziness as I had one, new in the bag
from a hamfest quite a while ago as a spare antenna. My plan after
I'm done playing with it as-is, is to extend it to a full wave 80m or
160m loop.

Check this article out.

You're right. My mistake. Suspend it among tree branches, etc., but keep
it away from buildings and metal.

From: xperts88
Topic: 4044 Message: 4144

Hi Rick,
Thank you very much for your excellent information and you show me very detailed and correct my knowledge to the antennas to use laddar line.
I have not enough space or install over 33ft so I will make the 102 feet G5RV for 10-80m first with 31 feet ladder line and will try this with a coax looking for RFI or burn something in the shack hi.
100 feet laddar line with holizontal element or dipole is not realistic solution to do multiband operation to me now.I use this for IOTA or portable use in the future so light weight wire antenna is a mast to install any place I've never seen.
Had been usually used my designed OCF dipole with plugs and jacks like Anderson DC terminals as to switch on/off the length of dipole asymmetrically case by case.
No tower, I just have a 33ft fishing rods and bring all TRX A(M)TU, paddlet,4,8AH Li-ion batteries,coax, water,cookies alttogether packed myself when a boatman called a small ship to leave a port. I sometimes get tired of some wire it when works wrong even some verticals and so am looking for more effective light weight antenna for portable operation as well as installing that in my restricted garden at home.TU Tim.

From: pitbon
Topic: 4071 Message: 4145

Dan,

thanks for responding and sorry the delayed response.
Actually my HOA forbids antenna's so i am trying to keep it as low
profile so no one will complain! I would like for the G5RV to give me
10-40 meters if possible, i am studying for my General class license.
So when i upgrade it will there waiting for me. Ive heard some
stations coming in from colorado and Texas and Missouri so I know its
atleast functioning half way decent!
I just wasnt sure if my 90 degree bends should be at a certain length.

I am thinking also to try an attic antenna for maybe a specific band,
like either 20 or 40 and the same question applies.

Thanks for any info!

From: Callum M0MCX
Topic: 4096 Message: 4146

>>> as you say it gives a very good match on 70cm

James and I were talking about this last night (he lives nearby). He made a ¼ wave vertical for 2m which loads up on 70cms as it happens.

Q: Can one expect to match 50 ohm coax direct to a ¾ wave vertical for 70cms (which in real life is a ¼ wave for 2m inc ground plane radials)? Real life results last night demonstrated that for 2m, it was a fantastic little antenna but had little going for it on 70cms other than the fact that the SWR appears very low (terrible signal though).

We debated this topic and I wondered if the outside of the coax is assisting with the match, not the radials?

This □hairpin□ match business, I don□t know about it. I□ll have to do some digging because I□d like to match some weird lengths, not just ¼ wave occasionally.

Cheers,

Callum McCormick

Subject: RE: [ham-antennas] Re: 2m antenna

Hi Rick,

>> Incidently, a quarter wave antenna for 2 meters will also work as a 3/4 wave on 440 !

I've just built a ¼ wave for 2m and as you say it gives a very good match on 70cm. Software modeling predicts about a 6dbi gain (10m over ground) on the ¼ wave for 2m at about 3 deg radiation angle, This seems to be the case in real world tests against previous antennas.

If anyone wants a small very effective homebrew 2m antenna the ¼ wave vertical is a very good option.

Subject: Re: [ham-antennas] Re: 2m antenna

Just a quick note on 2 meter antennas. Odd multiples of a quarter wave are easier to match to 50 ohms, but multiples of halfwaves are high impedance (around 5000 ohms) and require some sort of matching network to match to a 50 ohm feedline such as the Jpole uses (quarter wave matching section) So, if you want to build a simple vertical for 2 meters that has a little gain, you could build a 3/4 wave ground plane with quarter wave ground radials. The 3/4 wave groundplane for 2 meters is about 58 inches tall with 20 inch radials that slope down at about a 45 degree angle. Incidently, a quarter wave antenna for 2 meters will also work as a 3/4 wave on 440 !

take a look at the pictures of my 5 element 2 meter beam.
<http://ph.groups.yahoo.com/group/ham-antennas/photos/browse/55ab>
I made a pair of 2 element beams based on the same design, but used
different mounting. One could make just the driven element as a vertical
dipole.
And can be made horizontal or vertical.
Materials can be almost any chunks of aluminum from rod to round or
square tubing.
I do not suggest using PVC for an antenna that will spend most of its
life in the sunlight. Can gradually get brittle and break when least
expected. Okay for intermittent use like trips or field days, etc....

Also, I do not like gain specifications that use DBi.
DBd is a true specification based on gain over a dipole.

4150. How do I process the end of the G5RV's leftover laddar line before my shack?

Yahoo group: ham-antennas (2008)
Date: 2008-02-15 03:19:26 UTC
From: xperts88
Topic: 4044 Message: 4150

Hi Karl and all again,
I understand all, thank you for your advices.
I just have amother little anxious matter how I should process ,
arrange the lefover end of the ladder line.
Because of the proper radiation from it and I heard
someone said me if I had a small space to pull down from 33 feet
fishing rod apex, I had better pull the line holizontally even form
zigzag and if I have enough leftovers (if it includes a coax and a
coax balun)to shack, the leftover length of the laddar line should
be bent with a few space in proper length about one feet doing zigzag.
the people says a zigzag folded ladderline cancel,negate then reduce
RF radiation from the part but it may keep the length of the ladder line
(as a 31 feet line of a 80m G5RV) Is this something like a linear
roading section? I just met the OM once at the hamfest yeare ago.
So please answer anything how to do myself or avoid this?
73 OMs Tim,

Hi Chris,
Thank you very much you show me Cebik's 135' multiband dipole instead
102' is better, I see all.It is about 5% shorter than that of full
size 80m dipole using coax.
Do you know the transfer coupling products Cebik recommends in the
market? there is only use the ladder line pull direct into the
tuner in a schack, this will another issue.To make two halls on the
wall for feed line terminals is prohibited here. The theory of your
and Cebik is very helpful.

4153. RE: [ham-antennas] VERTICAL ANTENNA

Yahoo group: ham-antennas (2008)
Date: 2008-02-15 09:28:33 UTC
From: Callum M0MCX
Topic: 4147 Message: 4153

Depending on frequency and whether you will have elevated tuned radials, start at around 10.25 meters and then start folding back /cutting.

Someone should invent a formula involving the speed of light and the wavelength!

:)

Callum.

Unless, of course, you simpy run it into a tuner with a balanced output, in which case the length isn´t critical at all. Strictly speaking it´s a matching stub, not a radiating element.

234/f where f is in mhz will give you the length in feet.

The company stopped manufacturing ham antennas shortly after that. I believe they then concentrated on military systems and eventually sold out to Raytheon.

The antennas were about 32 feet of telescoping thick wall aluminum with the capacity hat made of wire loops bolted to the top and the tuning units were adjusted with slugs. They were pretty effective for me. I bought them some months apart and when I put the first one up (in a late February ice storm), I got it tuned, then fired up the rig on 40m CW and called CQ. It was around 3 or 4 in the afternoon and VK6MR came back to me immediately--long path!

If money was no concern, I'd consider an 18HT from Hy-Gain. Especially for the low bands. Unless you can get a horizontal antenna to 130 feet (about 40m) for 80m and about twice that for 160m, they just don't work that well. For wave-lengths from 40m down, yagi arrays become more and more practical as frequency increases,

4159. Suggestions welcome re: all-band dipole

Yahoo group: ham-antennas (2008)
Date: 2008-02-16 16:29:41 UTC
From: lecontejoe
Topic: 4159 Message: 4159

Back in the day, back when I lived on property with trees, I put up a 135-foot long wire dipole, fed with ladder line, tuned with a Johnson Matchbox. Used it on 80 and 40, ran a tribander for 20-15-10.

After a few years of adventures and 28 moves (military service) -- including being wiped out in Hurricane Katrina -- we are building the place from which we will not leave. Problem is -- there's not a tree in sight and the house is one story with a hip roof (no gables to tie antennas onto).

http://www.schlatter.org/Nneck%20House/nneck%20house%20pg%201.htm

I am putting three structures on the lot:
-- house
-- garage to the right rear of the house
-- shed-workshop at the far left corner of the lot.
-- lot measures 135 wide X 240 deep.

The garage will be 24 X 30 with 100 amp service and I'm planning to build an 8 X 6 ham shack in the garage. If I tie one end of a 135-foot wire to a vent pipe on the back of the house roof I think I can run the wire to the garage where the center insulator will be tied to something on the roof, then, run the other leg of the wire out to the storage shed. This will result in a dipole that's fairly horizontal but viewed from above will be a slight V with center angle of around 160 degrees.

At the house I should be able to keep the wire 24-25 feet off the ground (house has 3 foot crawl space, 9 foot ceilings, 6/12 pitch roof puts the top of the roof 15 feet above the ceiling -- 3+9+15=27 feet to the peak of the roof). I can get only 20 feet at the garage and 16-18 feet at best at the shed (unless I stick up a pole on the shed to give me 25 or so feet).

Homeowner's association covenants do not restrict antennas. In fact, some folks have old TV antennas but I am concerned that I'll push the envelope with a dipole, tribander, and VHF and UHF Yagis.

So -- question is -- what is the smallest wire gauge I can get away with for a 135-ft dipole center-fed with ladder line? The ladder line will be obscured from view by the garage but I've got to use wire and rope for the body of the dipole that will be the least visible. I run only 100 watts.

I'm planning to stick two pieces of 3-inch PVC, each about 2 feet long, through the roof of the garage, one at each end -- like a vent pipe. Secure the PVC to a rafter with a U-bolt. Beneath the PVC,

secure a piece of doubled 3/4-inch plywood to several ceiling joists; bolt rotator to the plywood and run the mast up through the PVC -- put a tri-bander on one mast, VHF and UHF Yagis on the other. Masts will be long enough to clear top of garage roof while keeping the antennas as low profile as possible.

"The Wireman" sells a 26 guage stranded copperweld. It's pretty tough. I have one end tied to a tree that blows around a lot in the wind. It's very small and nearly invisible. I just wish it came in white (rather than black) then it really would be invisible. The Wireman does say that it's not recomended for 160m, but 80m and up are ok.

With your installation, all the supports are fixed, so the wind sway is minimal.

Another suggestion, plant some tress. Reaseach things to find out what kind of tress grow fast in your area. You can get establised tress from a nursery, for a $50 to $200 depending on the size. Fertilize & water them well and pray. I started using mine as antenna supports, only 3 years after they were planted.

Thanks -- I'll check out Wireman's wire.

Being retired, after we move in, hang pictures, and do all the other stuff associated with moving, I'll have time to experiment with antennas.

Another possiblity is two end-fed wires. I'll have a tribander for 20-25-10, so, I need a wire for 80 and 40. I'm thinking that maybe I could lay out a few 1/4 wave ground wire -- 2-3 each for 40 and 80, then, run a 1/4-wave end-feed 80-mtr wire from garage to shed and 1/4-wave 40-meter wire to the house -- it would look like a dipole with one end twice as long as the other but actually would be two antennas. With this arrangement, I'd have to connect/disconnect the 40 or 80 wire inside the shack when I changed bands.

We are planning to plant trees along the back and sides of the property line. Probably flowering trees -- dogwoods, Japanese cherries, and hollies.

Thanks again.

4162. Rig cutting off when I transmit on SSB - Update

Yahoo group: ham-antennas (2008)
Date: 2008-02-17 17:13:45 UTC
From: Jonathan Helis KB5IAV
Topic: 4162 Message: 4162

I previously started a thread here regarding how my rig would cut off when I was transmitting through my half wave open loop antenna. I tried grounding everything in the shack, cutting the twinlead length, putting a counterpoise on the tuner, and still no luck. I also put RF beads on the coaxes and power cables but it didn't help. A new power cable between the Astron RS20A power supply and the rig didn't help either.

I bought a dry dummy load last week and connected it up to my rig using an open connector on the antenna switch. The rig exhibited the same "cutting out" behavior. I checked my field strength meter and it registered no RF in the shack. Now I know it's probably not an RF in the shack issue. The only strange thing I noticed was the RF bead on the power lead seemed to vibrate when I was transmitting.

Since I've eliminated RF in the shack as being the reason for this, I need some ideas on where to look for trouble next, power supply or rig? Any suggesions?

Thanks for the help everyone here has been giving me to solve this problem.

Suggest you try a car battery to eliminate the power supply.

My 2 cents:

Unless you are planning to support the center insulator, the weight
of a 135' flattop is considerable. My preference to balance stealth
and longevity in this situation w/ be 16ga copperweld. I once had an
inverted- vee constructed from some 14ga hard-drawn copper that was
insulated w/ a light-gray insulation...it was darn near invibible
except for the insulators.

Also, if I were building a place from scratch and expected to stay
there for the foreseeable future, I'd plant some fast-growing trees
in a couple strategic locations for future use as antenna supports..

As has been suggested to you before by others here on the Group....(I think it was this Group)
" Try hooking your rig to a Battery for the power Source an see if that helps your problem "
Have you tried this approach yet ???
I know it might be a pain to get the car or truck battery in the shack there But it won't cost you anything an may help resolve your problem...Remember though, never sit a vehicle battery on the concrete floor because I have heard that it will kill the battery....
Good luck and 73's

Bill
kc8ilp

Also maybe try plugging the power supply into another Wall outlet...Maybe something wrong with the one it is plugged into now...It's a long shot but an easy try.....
I could be wrong But, I believe if a rig isn't getting enough power it will do the same type things that you are describing..The Rig does not Draw as much power (amps) in receive as it does on transmit even at 5 watts....most rigs (I think) will receive just fine on a little less than the recommended voltage. But as soon as you key the Mike. If the minimum recommended voltage isn't there it isn't going to Transmit and there may be problems such as you are describing. I'd be concentrating on that power supply....But I'm just guessing....

Jonathan Helis KB5IAV <kb5iav@...> wrote:
I previously started a thread here regarding how my rig would cut off
when I was transmitting through my half wave open loop antenna. I tried
grounding everything in the shack, cutting the twinlead length, putting
a counterpoise on the tuner, and still no luck. I also put RF beads on
the coaxes and power cables but it didn't help. A new power cable
between the Astron RS20A power supply and the rig didn't help either.

I bought a dry dummy load last week and connected it up to my rig using
an open connector on the antenna switch. The rig exhibited the same
"cutting out" behavior. I checked my field strength meter and it
registered no RF in the shack. Now I know it's probably not an RF in
the shack issue. The only strange thing I noticed was the RF bead on
the power lead seemed to vibrate when I was transmitting.

Since I've eliminated RF in the shack as being the reason for this, I
need some ideas on where to look for trouble next, power supply or rig?
Any suggesions?

Thanks for the help everyone here has been giving me to solve this problem.

I live in a 3rd story apartment and want to run a random wire antenna to a tree about 30 feet from my apartment. To help hide it I thought about using either 26 or 30 awg magnet wire. I'm running 100 watts using an sgc230 auto tuner. Would 26 or 30 awg wire be too thin to use or would it work?

I agree, I've experienced the same problem and turns out it was my power supply not supplying enough amps on the peaks. I upgraded the supply and problem solved.
Good luck,
Todd

Have you tried monitoring the voltage from you power supply while you transmit?

Subject: [ham-antennas] Rig cutting off when I transmit on SSB - Update

I previously started a thread here regarding how my rig would cut off

when I was transmitting through my half wave open loop antenna. I tried

grounding everything in the shack, cutting the twinlead length, putting

a counterpoise on the tuner, and still no luck. I also put RF beads on

the coaxes and power cables but it didn't help. A new power cable

between the Astron RS20A power supply and the rig didn't help either.

I bought a dry dummy load last week and connected it up to my rig using

an open connector on the antenna switch. The rig exhibited the same

"cutting out" behavior. I checked my field strength meter and it

registered no RF in the shack. Now I know it's probably not an RF in

the shack issue. The only strange thing I noticed was the RF bead on

the power lead seemed to vibrate when I was transmitting.

Since I've eliminated RF in the shack as being the reason for this, I

need some ideas on where to look for trouble next, power supply or rig?

Any suggesions?

Thanks for the help everyone here has been giving me to solve this problem.

The biggest problem with such antennas is that they tend to usd
the building and its internal wiring as counterpoise. If I were
doing this, I'd look for places to run two equal length wires and
feed them to a tuner's balanced outout with twinlead. If you can
run the wires at least 30 degrees from each other, they should
radiate fairly well and keep most of the RF energy outside.

Matt,

I have used a very small wire and it will work. I used tiny plastic covered alloy garden twine. It comes in 100m rolls for about £5 in garden shops in the UK. I☐m unsure of all the physics though. Bandwidth is almost irrelevant do to the SG230 (which I have also used with this) as I☐m sure it will have a bandwidth greater than your audio(!).

What about your ground? The SG230 needs a ground bigger than the antenna otherwise your could get all sorts of funnies ☐ including getting burned by the back of the microphone (yes, it happened to me) so perhaps instead of running one wire out, do you fancy going out.. then coming back and turning it into a closed loop?

Just go for it :)

Would it be better to have the loop vertical or horizontal? Also, is bigger better? I ask for the reason that if I do it vertical it will be in a square about 30 feet high by 10 feet wide. If I do it horizontal, first I'm gonna have to figure out how to get it into the trees. But if done, it would be in a triangle shape about 50 feet out, 50 feet across and 65 feet back.

4172. Long-wire in a tree.....

Yahoo group: ham-antennas (2008)
Date: 2008-02-18 15:11:19 UTC
From: Rob Thomson
Topic: 4172 Message: 4172

I am going to install a 140ft long inverted-L long wire (Marconi) with a homebrew remote tuner at the base.

I was considering putting the vertical section inside a 30ft fibre-glass pole and running it up the trunk of a 20ft pine tree that I have. This would have several advantages:

1. It is a ready made support - higher than anything that I would want to errect
2. Concealment
3. Hides the wire and prevents RF burns to my 2 toddlers
4. The base of the pine is almost waterproof already, making the sealing of the tuner and ground plane wires much less of an issue

The obvious question is what effect will the tree have on the antenna?

All advice welcome

Rob, G4LMW

Matt,

The vertical 30 x 10 isn☐t so good as the horizontal 50 x 50 x 65 which would be fantastic from 80m upwards (with an SG230 certainly).

Without going too deep, they would both actually radiate but in different ways and would tend to have peculiarities depending on the band however I would personally go with the horizontal. I☐m really quite jealous!

You might like to put a couple of springs fixed to the structure so that in the event the trees moved in the wind etc, you would get some ☐give☐ in the springs?

Shame you have to make this a stealth ☐ I would like to see this in a FlexWeave or heavier-duty wire ☐ but only for the durability. Certainly this would work damned well!

How high up would the 50 x 50 x 65 be?

4175. Is canal / lake water transparent to RF?

Yahoo group: ham-antennas (2008)
Date: 2008-02-18 16:30:31 UTC
From: Callum M0MCX
Topic: 4175 Message: 4175

James kindly modelled my vertical for the boat recently and mentioned that the canal water surrounding my boat would basically be transparent to RF because it's not salt water.

I suggested to him that we'd discuss this topic here.

Is he right?

By coincidence, this month's QST magazine has pictures of how a guy strung a horizontal loop using 'stealth' wire into his SGC-237 on the inside of his shack.

I agree, you would be best served to go with a loop for reasons of having it balanced for one, and the noise reduction features of a loop as well.

Make it as large a loop as you can, preferrably a full wavelength on the lowest band you want it to work well on. Shape isn't particularly critical, the object is to have as much area enclosed by the loop as close to a circle as possible. Symmetry helps with the performance, but it isn't the end of the world if you are in a compromise situation.

Even 20' high will work quite well for you as well, you won't be the biggest contest signal on the band...but if you wanted that, you would have bought acreage on top of a mountain somewhere. ;-)

The antenna would be between 30 to 40 feet high. There's a 4th tree that I would love to add to the loop that is in between the other 2 trees about 30 feet behind them to make it into a diamond shape but unfortunately it's on the other side of the power lines! It would be below the power lines by about 20 feet but still too close for comfort!

From: gadzooks.mike
Topic: 4172 Message: 4178

Someone did a study that I read on the Internet. Unfortunately, I can't find it again. Bottom line was that trees don't do much at all for or to antennas.

Allow me to model this: 50 x 50 x 65 feet (nearly 50 meters) at 40 feet sloping to 30. Hang on....

Subject: [ham-antennas] Re: stealth antenna

The antenna would be between 30 to 40 feet high. There's a 4th tree that I would love to add to the loop that is in between the other 2 trees about 30 feet behind them to make it into a diamond shape but unfortunately it's on the other side of the power lines! It would be below the power lines by about 20 feet but still too close for comfort!

There was an article in QST that addressed it. If you are really close to a tree or large branch, it can have an effect. Otherwise, it has effect, but certainly not like a steel or copper tube of the same size.

Matt,

Because it□s more than a half wave on 80m, it will work there quite well, actually a first class cloud burner on both 80m and 40m then it starts to develop some interesting lobes from 20m right up to 10m.

I□ll ship you the file. Download MMANA to have a play with it.

Callum.

Aadu,
I would put the antenna in the middle of your garden, use equal length radials (I'm assuming
you're going to bury them) spaced evenly around, and then bend (as needed) any radials that
won't quite fit. Just make sure you don't overlap any radials when you are laying out the bent
ones. If you put the antenna in the corner, you will wind up with a strange radiation pattern,
and you don't know whether your neighbor has metal pipes, etc. just over the wall that may
detune your antenna. Good luck! 73, Jim

4184. Re: [ham-antennas] Re: 40m vertical radials

Remember, when ground mounting a vertical it is not necessary to make the radials resonate at any frequency. It is more important to have more radials at least 1/8 wavelenght at the lowest frequency than to have resonate radials (opposite of above ground mounted radials). The purpose of radials in a ground mounted vertical is capacitave coupling to actual ground which is the second half of your antenna.

> kc8ilp
>
> Also maybe try plugging the power supply into another Wall outlet...Maybe something wrong with the one it is plugged into now...It's a long shot but an easy try.....
> I could be wrong But, I believe if a rig isn't getting enough power it will do the same type things that you are describing..The Rig does not Draw as much power (amps) in receive as it does on transmit even at 5 watts....most rigs (I think) will receive just fine on a little less than the recommended voltage. But as soon as you key the Mike. If the minimum recommended voltage isn't there it isn't going to Transmit and there may be problems such as you are describing. I'd be concentrating on that power supply....But I'm just guessing....

I haven't tried the car battery yet, but I did try 2 other wall outlets in the same room, and it didn't help.

I'm thinking power supply too, but again still not sure. I was able to recreate the problem by loosening and tightening the connector going into the rig while transmitting into the dummy load. I'm thinking power is shutting down from the power supply. Fixing this is going to be in the back burner for a little while, since I just spent $500 getting my car fixed.

Thanks for the help.

I'm coming to the conclusion it's a power supply issue as well, based on some tests I've made and others' comments. I might pull the multimeter out and see what the power supply does on transmit, maybe that will tell me.

4188. Looking for stealth copper line and clad three to six paraller lines

Yahoo group: ham-antennas (2008)
Date: 2008-02-19 04:50:24 UTC
From: xperts88
Topic: 4188 Message: 4188

Hi all,I'm Tim again,
I am looking for an antiweatherable thin strong stranded (not steel wire)copper wire about #16 to 20AWG for another long but stealth wire antenna.
Could anyone recommend me some wires?

Also would like to have three or five to six paraller lines coated together about #16 to 20AWG around.I used a paraller lines for PC to make antenna and radials for backpaking mobile.It was cut and I think PC paraller lines are not repeatable or reliable for a trip.
Could you show me some shops or firms?
73/88 Tim, AH2E

4189. Adding a wire Reflector element to a 80m orizzontal wire Dipole

Yahoo group: ham-antennas (2008)
Date: 2008-02-19 13:08:42 UTC
From: Massimiliano DP
Topic: 4189 Message: 4189

antennas-hamDear colleagues, I am a neo-radioamateur.
Sorry for my broken English.

I was thinking about adding a Reflector element to my simple 80m wire Dipole to convert it to a 2 elements yagi.

The present dipole arms are 18.8 meters each (61.67 feet each), the wire section is 1.5mm (0.06 inches section) + plastic shield.

It is now perfectly tuned on 3.790 MHz, SWR 1:1

It has a 1:1 home made Balun at the centre.

It is only 20m (about 65 feet) from the ground, hanged to 2 trees. It is orizzontal, parallel to the sloping ground and, naturally, the dipole is also sloping but mainly parallel to the "terrace" sloping ground. The ground is mostly wet, I am in a mountain area (Apennines mountains Range 850m slm). The dipole direction is east / west.

I gave you complete info because I know that there are experts hams able to check it with special antennas softwares that I am, at the moment, unable to use "properly". Please feel free to ask any question & in case, if you like, pls check my web site for the pics of my QTH terrain conformation.

What will you suggest for the Reflector length and distance from the radiating element ?

Thanks for this very useful and interesting forum and for any future help.

Max,

Modelling this antenna with a reflector of exactly 40m long, would achieve very good high angle gain but will increase the resonant frequency (you may need to lengthen the antenna a small amount).

However, a dipole for 3.8Mhz at nearly 20m height is a great antenna anyway - if you really want VERY(!) strong local (under 1,000 kms) signals then the reflector on the ground will help a lot. In this configuration, it is called an NVIS antenna. There is an NVIS Yahoo group. You might like to ask there too?

Good luck,

Callum McCormick

Dear Callum M0MCX, thanks for your wise advice. I just have come back from the garden where I took some measures and I checked if I can use 2 trees to hang the added reflector to my dipole. Ok, thanks, I will tune as you suggested lengthening the dipole. Regarding the NVIS antenna I did not understand if it is good also for low angle radiation (for dx calls). Actually, my dream would be having an antenna that would heavily attenuate local signals in favour of Dx signals... is this just a dream ? I will look around about the NVIS features.
Thanks again Callum,

If you want DX then DO NOT use the reflector!

If you want to attenuate local signals, use a vertical antenna (http://www.m0mcx.co.uk/?p=100). The DX properties of a good vertical are about the same (maybe better) as a dipole at 20 meters but with less gain from above.

You will not save space with a good vertical - you need lots of space for the radials (or a ground based system).

Regards,

Callum McCormick

Topic: 4189 Message: 4195

Thanks, very interesting, in your experience, do you believe that a 20m vertical for 80m is better than a 2 elements 80m monoband yagi? I read somewhere that a 80m Yagi @ 20m on slope terrain at mountains high altitude was better than a vertical (lower angle with the yagi with this conditions).

Do you suggest that, at only 20m high, adding an element will increase the elevation angle ? I erroneously thought the contrary. What about 3 elements? I probably have the exact space for 3 parallel wires..
I did not know than a 2 or 3 element yagi was worst than a 20m vertical antenna for Dx.
Very interesting, thanks.

I did have a look at your nice vertical antenna pictures.
By `ground based system' instead of the radials I believe that you mean salty water or very conductive ground ..or do you mean something different? Thanks again Callum.

Callum, he's talking about an adjacent reflector, not one directly under his dipole. I've never tried it with 80 meters, but NEC modelling a 20 meter dipole vs. 20 meter Yagi fairly close to earth shows that the added reflector (or director, if you choose to go that route) does actually bring down the angle of radiation some. A dipole has a fair bit of radiation straight up, a two-element Yagi has little that goes straight up. Both dependent on height off ground, of course.

Max / Dave,

Ah! Yes - of course, a Yagi would be excellent! An amazing antenna if you have the engineering to do this.

Of course, a fixed yagi to a tree or something would work fine :)

Apologies for confusion - I was an NVIS nut in another life!!

The Hamstick dipole works horizontal or vertical. It is just a center fed shortened dipole. I am assuming that when you say vertical you are talking one up and one down from the feed point. If you are talking both upward then it wouldn't really work.

I wouldn't expect a big difference in either as the capture length is about the same. The Hamsticks will be easier to get working but the whip will give full QSY. Don't expect much bandwidth out of the hamsticks on 80 and 40 unless using a tuner as the 2.0:1 bandwidth is only about 15khz on 80M and 30KHz on 40m. With a tuner you can get about 150-200KHz on 80M and 40M. 20M the hamstick can pretty much cover the complete phone band without the tuner.

When you add a reflector or director to a dipole, the tendency is for
the dipole's feed-point impedance to go down, not up. I'd keep the
1:1 balun at the feed point and use a tuner. Simply matching the
impedance however works is fine - a Yagi's directionality is not
impacted by an impedance mismatch of the driven element, it is
affected only by the length of the reflector.

The ARRL Antenna book has a chapter on element lengths for Yagis.

4208. RE: [ham-antennas] random wire tuner vs hamsticks

Yahoo group: ham-antennas (2008)
Date: 2008-02-20 15:50:54 UTC
From: Callum M0MCX
Topic: 4199 Message: 4208

>>> Don't expect much bandwidth out of the hamsticks on 80 and 40 unless using a tuner

.. and then, you can only fool the radio into thinking it's got a decent 50 ohm antenna. We're back to the argument of heating coax up and running inefficient antennas outside the working SWR curve.

Personally, I'd go for an 8.5 foot whip and an SG230 or similar - you have infinite bandwidth and could go from 160m to 10m.

Callum.

Subject: Re: [ham-antennas] random wire tuner vs hamsticks

I wouldn't expect a big difference in either as the capture length is about the same. The Hamsticks will be easier to get working but the whip will give full QSY. Don't expect much bandwidth out of the hamsticks on 80 and 40 unless using a tuner as the 2.0:1 bandwidth is only about 15khz on 80M and 30KHz on 40m. With a tuner you can get about 150-200KHz on 80M and 40M. 20M the hamstick can pretty much cover the complete phone band without the tuner.

From: john_tartar
Topic: 4189 Message: 4209

I will try to answer your question directly

Put a reflector approx 6 meters behind the driven element.
Each leg of the reflector should be 20.2 meters each.

This will give you about 4db of gain, and improve your take off angle
for DX.

Of course that will be a uni directoal antenna. If you want to be
albe to change the direction you can add a capacitor that can be
switched with a remote relay. A 500pf capacitor in series the
resonace of the reflector witll change and it will act as a director,
thus reversing the direction of the antenna. Shorting the capcitor
with a relay change it back to a director.

It is orizzontal, parallel to the sloping ground and, naturally, the
dipole is also sloping but mainly parallel to the "terrace" sloping
ground. The ground is mostly wet, I am in a mountain area (Apennines
mountains Range 850m slm). The dipole direction is east / west.

From: Chris
Topic: 4199 Message: 4210

Just to qualify this. I run an SGC-237 with a 102" whip.

In that configuration it works pretty well 20m and up in frequency.
Lots of contacts on 20m and 17m from the east coast of the US into the
Mediterranean and the Baltics, as well as into Europe.

For 40m it will tune, but not radiate much. By adding another 3' mast
extension under the whip, the signal is much improved, however it is
too tall to drive around with at that point. It is just under but
close to the 16' DOT clearance limit and bangs on anything you pass
by.

For 80m it will tune either way, but radiates pretty much nothing at all.

For 160m, I never even tried.

If you even get 1W out of 100W on 80m with this configuration I'd be amazed.

I like the combination, it's very convenient and with the whip, also
sturdy. A dedicated mono-band with a Hi-Q coil like a Bug catcher
will be far more efficient on the lower bands as would a full sized
screwdriver type antenna.

Dear John, this is very interesting, thanks. Let see if I got all right:

You suggested placing the reflector only 6 meters from the dipole ?
That is very good because I was thinking about placing the reflector 21 meters away !
(If the elements are so near I can even think about adding an additional director)..

Can you kindly explain a bit more about this reflector length and distance considering my dipole measures?
Did you get it with a software or from some book or personal experience ?

Very interesting also the switchable 500pF capacitor to reverse the antenna direction..
In your view can I place the C. inside my station and short it with a switch or it is better to place it near the feeding point?
Will I have to place it in series to the coaxial cable core or in parallel between shield and coax core ?
Sorry for this unskilled questions & thanks a lot for any widening of this topic.

Max

In a mobile environment the loss caused by SWR loss in pretty small. If you look at the loss of RG58 for a 20ft run with a 10:1 SWR (limit on a LDG tuner) on 80M you only have .5 db of loss from swr and a total loss of .656db. You can eliminate most of this loss by moving the tuner close to the base of the antenna. Changing the coax length to 1ft drops the SWR loss to .028db and the total loss to .035db. For reference the coax loss at 1:1 swr on a 20ft run is .14db and you would have that with either solution.

The voltage that will appear at the base of the hamstick at a 10:1 swr is much lower than what will be there for a CB whip which is why I said he hamstick solution is easier to get working. But I agree the SGC237 gives a much more flexible solution.

On the other hand I have gotten pretty good reports and a lot of surprise that I was running a mobile when I used a 40M or 80M hamstick combined with a LDG tuner. Granted we are not talking real DX but I can usually work about halfway across the US on 80M while mobile. (i.e. OK to NC or CA, AZ to CA or MO,TX). Considering we are talking an antenna that is only about 1/40th of a wave length I don't consider that bad.

OK, let me play for a moment..

Mismatch of 5:1 SWR on 40m band with RG213 at 100 watts: I'll get 76 watts out the antenna and 24 watts to heat the cable up.

Is that right?

By the way, I was calculating that for 30 meters of RG213..

This is interesting because even at 1:5 SWR, this calculator is suggesting
that for 30 meters of 213 at 7 Mhz, I'll still lose 20 watts in the cable.

Seems a bit steep to me!

about half the loss is just the coax itself without even considering the
loss to SWR. That is also with Belden 8267. Wireman isn't quite as bad.

4222. Want to build vertical

Yahoo group: ham-antennas (2008)
Date: 2008-02-21 03:30:00 UTC
From: pitbon
Topic: 4222 Message: 4222

Ok I am really new to antenna building and I want to build a semi hidden verical...low cost antenna.
The idea i have is to use some pvc and paint it camo and mount it to the back side of a tree. My tree is about 20 feet tall or so but i think i could go a few feet above the tree with the antenna without causing any concern from neighbors or my HOA....I hope..

Any suggestions or web links someone might have would be awesome.

What i would like is a minimum of 20 meters since i am studying for my General ticket. I have a dipole that i cn tune in somne 40 and 20 meters but i would like to pull the signals in better and was hoping a vertical might do that.

I have a length (125ft) of RG213 that a fellow Ham friend gave me so I'm good there, Should I buy an antenna or can i make one fairly cheap...(i hope).

Thanks for any and all help it will all be considered!

Don□t paint PVC, you□re wasting your time (unless you use plastic primer and all sorts). Suggest you use a 30 foot fishing pole blank and just shove it that against the tree and hold in place with bungee straps or something (at least as an experiment). In this country, I can get fishing poles for about £20 ($40 dollars). In Europe, SpiderBeam do 18 meter (60 foot) specialist fishing rod type technology verticals precisely for this. I have the 12m version.

Anyway, mildly helically wind some wire up it (seems to stop the wire looking untidy) and use insulation tape to hold the wire onto the rod (or get creative and put the wire inside the fishing rod blank..? Remember that in time, the fishing rod sections can collapse inwards to each other so tape these sections together.

That□s the easy bit. Now you have a ground system to install. Start reading and get your mind around how you will achieve that □ or get an elevated radials system on the go. There□s a big choice out there and the topic is vast.

Or.. Use the top of your fishing pole as the top of a doublet and install ladder line up to the top with a tuner at the bottom (or in the shack) □ but don□t use coax for that solution, only ladder line. Wait a minute.. What about a G5RV? That works too □ it was my first antenna and was so easy.

Cheers,

Callum McCormick

Subject: [ham-antennas] Want to build vertical

Ok I am really new to antenna building and I want to build a semi hidden verical...low cost antenna.
The idea i have is to use some pvc and paint it camo and mount it to the back side of a tree. My tree is about 20 feet tall or so but i think i could go a few feet above the tree with the antenna without causing any concern from neighbors or my HOA....I hope..

Any suggestions or web links someone might have would be awesome.

What i would like is a minimum of 20 meters since i am studying for my General ticket. I have a dipole that i cn tune in somne 40 and 20

meters but i would like to pull the signals in better and was hoping a vertical might do that.

I have a length (125ft) of RG213 that a fellow Ham friend gave me so I'm good there, Should I buy an antenna or can i make one fairly cheap...(i hope).

Thanks for any and all help it will all be considered!

As for a Stealth antenna wire just buy a roll of Electric Fence wire at your local farm and home store.. You Don't need copper wire for an antenna. Sure copper may work just a little better but you are looking for a Stealth Antenna.
If you opt for parallel lies then you will Loose your Stealth. The insulation will make it thick and not help at all.

Hi Dean, I know what you would advise me as a stealth radio.
It may be the best solution,
But for my acuisitive nature to 3 paraller lines is unlike below #20
or thiner ones.
I think the black coated ones.
See http://www.hechinger.com/web/catalog/product_detail.aspx?pid
=186707&cm_ven=PriceGrabber&cm_cat=Building-Remodeling&cm_pla=Philips
+Accessories&cm_ite=Philips+Accessories-Electrical-186707&cid
=1E59F7C96DEFBBF206E93CD65E0D5DFB
This every line is just 26 AWG line for Philips Rotator
What I want is unlike PC or this paraller ones
but thicker ones.
Does anyone have some information please?

yes, vertical will also work, though a bit trickier mounting, as
proximity to other objects has an effect on them.
In 2002, I made a number of conatcts from a stationary mobile using an
Ironhorse 20 meter whip on a large magnet mount. This was in the evening
from Washington state.
Contacts included Sweden, Finland and Russia.
Radio was an Icom 706 MK II G at about 100 watts.
This was in mid to late September.
Time of the year, band conditions and so on can make a lot of differences.

I have also talked some fair distances on 6 meters using a hamstick on
the magnet mount on my tin roof, at an angle due to the slope of the roof.

I suggest using an analyzer to adjust the antennas if possible, otherwise
an SWR meter can work.
I had set up the 20 meter Iron Horse whip using the SWR graph in the 706.
Oh yes, moving it can change the SWR due to other factors.
YMMV

Why are we strapping poles to trees? The tree IS the vertical support. How about hang a rope from a branch, with an insulator at the bottom, then suspend 20 gauge copperweld downward from there? I've got 20 gauge copperweld in the air right now at 40 feet high and can't see it. At the bottom of whatever length of copperweld you use, a base insulating system and two tuned radials will make it a dynamite DX antenna.

4230. Windom Antenna Question, G5RV Antenna

Yahoo group: ham-antennas (2008)
Date: 2008-02-22 14:30:52 UTC
From: gary jamerson
Topic: 4230 Message: 4230

Hello! To all,

I live in a 2 story house In a subdivision that has antenna restrictions. So my options are:
My attic is 10' to 20' high in different areas would it be safe to use these antennas? I just don't want to burn my house down.

Windom Antenna Question:

Is this antenna safe in a attic that is 10 to 20 ft. high in different areas? I will also need to put it in a Z shape.

G5RV Antenna Question:

I have this antenna and I was planning to place it as an inverted V and the ends placed similar to a Z,but due to the slope of the roof it is not 50' long on either side of the slope. So the ends of the the antenna would have to trail off horizontally.

Would appreciate any advice.

Thanks.

Gary J.

4231. Flag Pole Verticle Antenna

Yahoo group: ham-antennas (2008)
Date: 2008-02-22 15:09:02 UTC
From: gary jamerson
Topic: 4231 Message: 4231

Hello! Again,

I forgot to include one other question. I have to check and see if I can install a flag pole. Then i could run a antenna inside the flag pole.

I have a few questions on the flag pole antenna.

1.Does the grounding rod need to be near the base of the flag pole? Or can I have the grounding rod near the house? I think I might know the answer. It would have to be near the base of the flag pole where the radials be.

2.Do I have to place a SGC-237 antenna coupler near the base of the antenna or can I use my LDG Z-100 ULTRA or LDG-Z-11 PRO at end of the coax in the 2nd story ham shack? I would be running the coax under ground about 150 -200 ft. and thendun up some coax behind an aluminum gutter toa second story window and then into the shack.

3. What coax would you recommend for for the 150-200 ft. below ground coax. I would think it would have to be some very low loss coax.

4.Behind the gutter I would like to place some coax that is small in diameter and also it needs to be low loss coax cable also.

I would like your thoughts,Ideas and advice on this matter. In other words your help.

Thanks in advance for your help.

Gary J

I wouldn't hesitate with a few caveats.

Use standoff insulators, don't let the wire contact the wood rafters directly.

Try to avoid close proximity to metal, be it duct work or pipe as it will detune the antenna.

Would recommend against a G5RV since you can't fully flat-top it and allow the window line portion to hang directly down from it as designed. They are a compromise antenna to begin with, but if you start crumpling up ladder line, it will make a mess of the performance. You really need to let that ladder line hang straight and free of the feed point and I think it is roughly 32 feet long. They also aren't particularly great performers in an inverted V either. I prefer the Windom OCF 4:1 balun type vs the G5RV if you need to do a V or other geometry tricks to make it fit.

A great attic antenna is as big of a loop of wire you can fit in the space, and run with a wide range auto tuner like an SGC-237. You run the coax and power leads up to the attic and place the tuner right at the feed point of the loop. You get a versatile and balanced antenna out of it. Just watch the power limitations with auto tuners, only run a 100W rig with them.

I would say an auto tuner at the feed point would have lower losses than tuning the feed line inside the shack.

'full size' coax as in 9913/lmr-400/213U would hide behind a gutter well, I wouldn't compromise with mini-8 there either.

The ground should be at the feed point as it is an RF ground in this situation. Get some fine wire and lay it out and tuck it into your lawn as well. Make yourself say 4 radials 1/4 wave at the lowest band you want to work as a minimum. It will help you out a lot. Radials for at least 40m and 20m would probably be a good idea and you would appreciate the effort vs the performance increase you will see.

There's always the Steppir BigIR too, wonder if you could get away with rigging some small plastic pulley and a small flag on one of those? ;-).

Put the time in once and it will pay out for a long time.

From: Greg
Topic: 4231 Message: 4235

Hi Gary!
You might want to take a look at this article:
http://www.dxengineering.com/pdf/flagpole_antenna.pdf
<http://www.dxengineering.com/pdf/flagpole_antenna.pdf>

4237. Re: Want to build vertical

Yahoo group: ham-antennas (2008)
Date: 2008-02-22 18:16:42 UTC
From: Dave
Topic: 4222 Message: 4237

LOL! OK, I got it...small tree, not tall enough. Duh. I used to be in that situation, I *could* have remembered it!

One of my pals in California stuck a pole in a tree - or rather, paid someone to do it, as he's blind. That was 20 years ago. The tree has grown up past the pole and the antenna is now embedded in the tree. But he doesn't care, it's just his VHF/UHF antenna and he reaches the local repeaters fine.

73,

> Have you tried monitoring the voltage from you power supply while you transmit?

I just got around to trying that. I monitored the voltage from the power supply using a multimeter. While just listening, the power supply is at either 13.83 or 13.81 volts but when I transmit on lower power, the voltage drops slightly and when it cuts out, the meter registers a drop too.

Definitely looking like a power problem for sure. I also monitored the voltage coming out of my AC outlet and it drops slightly too when transmitting.

Definitely looks like a power issue.

4239. Hamstick antenna

Yahoo group: ham-antennas (2008)
Date: 2008-02-22 21:39:16 UTC
From: davidnapier2
Topic: 4239 Message: 4239

I have a Tentec Scout model 555 and just bought a Hamstick for 20m,my question is this,what is best way to tune the antenna to desired freq.? i've tried doing it the way instructions that came with antenna,said to do it,by sliding the whip up or down,but cannot find proper setting to get resonate freq. SWR goes off scale!! Any help[would be sincerly appreciated!!! David/KA4ZUC

PS.The hamstick is not mounted mobile,ive mounted it outside my window.

4240. Re: Hamstick antenna

Hi David,

Normally the automobile body would be the counterpoise for that type of antenna. What are you using for a counterpoise?

From: Mark, KJ7BS
Topic: 4239 Message: 4241

You really need to tune it where it will be mounted for operations. I'm not ssurprised you are having a difficult time tuning the Hamstick. It needs an image plane to work against (the other half of the antenna).

If you plan to use it mobile, then tune the Hamstick on the vehicle. The Hamstick uses the vehicle as the image plane (ground plane/radial/counterpoise).

If you plan to leave the Hamstick outside your window, you should add a tuned radial before attempting to tune the antenna.

If you switch between fixed and mobile operation, you will need to re-tune the antenna for that image plane.

Stop by the website of Alan K0BG http://www.k0bg.com , who is considered the leading authority in mobile operation and mobile antenna operations, and read about Antenna Efficency and Antenna Matching.

4242. Wattmeters and SWR Bridges FS

Yahoo group: ham-antennas (2008)
Date: 2008-02-23 00:35:57 UTC
From: Ken Simpson, W8EK
Topic: 3588 Message: 4242

Wattmeters and SWR Bridges For Sale:

Daiwa CN-520 "Cross needle" Wattmeter
This wattmeter does it all. It covers from 1.8 to 60 MHz, which means this one meter will measure power on all HF ham frequencies, plus six meters. It would be ideal for some of the new multiband rigs that have 1.8 to 55 MHz coming from one antenna connector, and 2 meters and 440 MHz from a separate connector. It has 2 power scales of 2000, and 200 watts on forward power, and 400 or 40 watts reflected, and uses a nice cross needle meter to read both forward and reflected power at the same time, with a cross scale for SWR. It works great, and looks OK also. $50

Heath HM-102 HF wattmeter.
Covers 1.8 to 30 MHz, with 200 W and 2000 W full scale. It can also be used to check SWR, and has a remote sensor that can either be left inside the meter, or separated from the actual meter by about 3 feet. SO-239 connectors in and out. This particular meter works fine and is in good shape. With paper work included for $38.

Micronta 21-520 A, HF wattmeter with two large meters
This is an HF wattmeter that covers from 3 to 30 MHz, with full scale power readings of 10, 100, and 1000 watts. Two LARGE meters -- one reads forward power and one reads reflected power -- both at the same time. This gives the same info as some of the cross needle meters, but many people find it is easier to read.
It has a remote sensor, with about 3 feet of cable to connect to the meter itself.
This particular meter works fine, and looks very, very nice. $50

Heath HM-15 SWR Bridge
This unit matches the Heath SB (and also HW) line in styling. It is an SWR Bridge that covers from 160 thru 6 meters, with SO-239 connectors on the back. The front has the meter on the left, and two knobs to the right. It is the same size as the HD-15 phone patch. This one is in very nice shape.
Paper work included for $20.

Heath AM-2
This HF SWR Bridge matches the DX-40, although it can be used with any HF transmitter. It is about 8 inches

wide and 4.5 inches high, with the meter in the middle,
and a gray colored knob at each side near the bottom.
It covers 160 thru 2 meters and will handle full power.
This particular unit is in good shape.
Paper work is included for $18.

Midland 23-126
This SWR bridge has a single meter, and a switch to switch
between forward and reflected power. It can also be used for
a field strength meter. This one works fine, and looks great
also. $15

Archer Field Strength / SWR meter
This is a fairly generic HF SWR Bridge. It is in a nice
sloping panel enclosure with a wood grain finish. $10

Prices do not include shipping from Florida.

Thanks.

Gary,

It's a life-time of learning which is what makes it great fun.

The trick is to build lots of stuff and keep playing. Most of my antennas didn't work as planned. You soon learn!

This weekend, I'm trying a 40 foot fibreglass whip in the garden with 8 elevated radials 7 feet above ground fed with an SG-230 Smartuner. It's not working too badly!

Just get some reels of copper wire and start right now :)

4245. Re: Windom Antenna Question, G5RV Antenna

Yahoo group: ham-antennas (2008)
Date: 2008-02-23 17:55:54 UTC
From: Brian Hall
Topic: 4230 Message: 4245

I would second the nomination of a loop antenna w/wide range tuner...SGC Models are great, but expensive.

I would also recommend placing it outdoors. If you trace the eaves and outline of your roofline including the peaks at either end, you can add more wire than otherwise. You can route the antenna wire under the eaves, in the gutters, and even beneath shingles, so it's pretty stealthy...I installed my loop after Thanksgiving one year and everyone assumed I was hanging Christmas lights. The coax connection can be routed down a gutter downspout to a first floor or basement shack, or thru a vent pipe on the roof. In my installation, I had a PVC vent pipe very close to one corner of the roof and wrapped about 8 turns of coax around it before connecting to the antenna (to form a choke balun (it cured some RFI problems I was having in the shack).

I TOO WANT TO SAY A "BIG THANK YOU"!!! TO ALL HERE THAT ARE SO WILLING TO HELP OTHERS!!! I'VE BEEN LICENSED SINCE 1982,BUT HAVE BEEN INACTIVE SINCE 1991,BUT NOW AM BACK!! JUST THE OPPOSITE ATTITUDE IS WHAT CAUSED ME TO GO INACTIVE!! THAT AMONG OTHER THINGS!!,AGAIN,MANY THANKS FOR THE HELP THAT IS BEING GIVEN HERE!! DAVID NAPIER/KA4ZUC

Hi Brian,

Last October I did exactly what you described and got away with stringing my coated wire 16 ft up under the eaves all the way around my single story house. I then ran ladder line down the wall to the shack window. It connects to a 4:1 balun and I run a 3 ft cable through the window to the transceiver. I can get close to a 1:1 SWR on all the major bands The problem is, I can't get much of a signal coming in or going out. If anyone has thoughts I'd love to hear them. Right now the loop is pretty much useless!

How long is the loop?

What does it look like when you sweep it with an analyzer?

What bands have you tried it on?

You are hopefully aware that propagation is just horrible at this
stage of the sun spot cycle? It can be very hit or miss and if you
are timing your radio use at the wrong times these days it can be very
frustrating.

4249. vertical comparisons?

Yahoo group: ham-antennas (2008)
Date: 2008-02-23 23:57:37 UTC
From: W0DXZ@aol.com
Topic: 3186 Message: 4249

I live in Sun City AZ, and am going to put up a 40-10M vertical. I have to put it up at "gutter height", about 8 feet. right next to the house. Cannot ground mount it. And, it cannot need guy wires. So...
I was thinking of either the Hustler 4-BTV, with some radials running along my roof, not a big problem,
or
older R7,,, recommended by several friends. no radials needed at 8 feet. If I can find a used one, as they are no longer made.

Any recommendations for verticals, or comparisons of these two? given these parameters,, (mounted at 8 feet or so, and can't use/need guy wires, but radials on roof of house OK)

Bob W0DXZ
AZ

The loop is just under 200 ft long. I collected SWR data at 0.2 MHz intervals reading through the coax and balun without a tuner from 1.8 MHz to 30 MHz. SWR ranged from 13 down to 1.1 depending of course on frequency. Troughs were at 3.0, 6.4, 10.2, 16.6, 19.8, 23.6, 29.4 and 35.2 MHz and were all SWR 3.0 or less. The auto tuner on my Kenwood TS-440 easily tuned the amateur bands at 80 meters, 40m, 30m, 20m, 17m, 15m, 12m, and 10 meters! I have the data in a spread sheet. email me directly and I'll send you a copy.

Ah o.k. interesting.

Just from what you stated, the low points are falling sort of out of
the bands. You could try adding some more wire or trimming it a bit
shorter.

That length of wire in rough numbers should work quite nicely 40m and
up and at least load for 80m regional.

Take a look at this calculator and see what the figures tell you.

http://ka1fsb.home.att.net/loopcalc.html

OK, but what should it tell me? As long as my auto tuner can get the SWR
below 1.5 I should be OK, no?

From: Chris
Topic: 4230 Message: 4253

That is sort of correct.

With coax feeding a balun, if you can get the antenna system to have the best SWR possible on the bands you want to work without using the tuner, you will have better efficiency.

High SWR with coax feeds means losses in the feed line.

If you were feeding that loop with ladder or window line directly using a balanced tuner, you would have an even more efficient system as the losses are FAR lower with balanced feed line vs coax.

Roughly, I think your loop works out to be a full wave on 5.025Mhz if I recall what the calculator was telling me. That's sort of in-between the way it falls in the ham bands. Your tuner will make your radio happy feeding that load, but that doesn't mean it's necessarily an efficient system.

Another example, though far more extreme, my mobile uses an auto tuner and basically a CB whip as an antenna. I can get a tuner match for 80m with that configuration so the radio is happy to transmit into that load. By the time all the losses hit, with my 100W radio I'd be lucky to have 5W ERP.

At home I run a 102' doublet, which once was a G5RV. I cut the balun off the bottom of the ladder line and just extended that 450Ohm window line right into the shack to my manual tuner's balanced outputs. I saw immediate signal report improvements. It works o.k. 80m through 15m and loads up on 160m for almost the whole band...but on 160m I'm really not radiating much of a signal because it is so far from resonance.

Someone smarter than me can jump in and give better loss figures in detail possibly but in a nutshell that's basically what I understand is going on here.

4254. Re: [ham-antennas] Re: Windom Antenna Question, G5RV Antenna

Yahoo group: ham-antennas (2008)
Date: 2008-02-24 15:27:17 UTC
From: Karl Moll
Topic: 4230 Message: 4254

Thanks. I understand.

But since I'm only using 3 ft of coax, doesn't that mean my losses would be very small indeed? I run my ladder line all the way to the shack window and only then through a balun to the coax and in to the transceiver. Regarding the match, I did check my data again and I get the following SWR values at the center of each of the ham bands: 1.9 MHz SWR=25, 3.8 MHz SWR=6.8, 7.2 MHz SWR=14.0, 14.2 MHz SWR=6.9, 21.2 MHz SWR=7.5, 29.0 MHz SWR=6.5. That's with the balun and 3 ft of coax in place. All of these by the way are easily handled by my auto tuner. Lastly, yes my loop is resonant at around 5MHz, which I could adjust by adding or trimming. Since its tacked up under the eaves, it would be a pain to adjust, but it could be done. At best however, I could only trim it to match one frequency on one ham band. That does nothing for the efficiency on the other bands right?

I'm really happy to be getting some insights from you. I appreciate it.

4255. Force 12 Flagpole Antenna

Yahoo group: ham-antennas (2008)
Date: 2008-02-24 23:36:15 UTC
From: gary jamerson
Topic: 4255 Message: 4255

Hello,

Has anybody used a Force 12 Flagpole antenna? Would you recommend it for a stealth antenna in a covenant restricted subdivision?

Thanks for your comments on this antenna.

Gary J.

A "Sky Loop" is a full wave loop and would be directional straight up. This is great for NVIS operation at or just below the critical frequency (ususally somewhere between 4 and 12 MHz).

On 10 Meters this would be great for receiving "mode A" satalites but would not be so great for terrestial communications.

Better for earth bound communications would be a 1/2 wave loop. Thsi wld be an omni-directional antenna with a radiation pattern similar to that of a "Halo".

From: Callum M0MCX
Topic: 4259 Message: 4262

I recently discovered that vertical delta-loops need a good close ground, just like a vertical - I tried a vertical square loop in my attic once for 10m and it was hopeless. It should have been mounted closer to the ground - and then it defeated the object.

Agreed. Don't do it. I have prepared a plot for you to compare 10m loop -vs- 10m dipole, both at 8 meters (25 feet or so).

The dipole will give you up to 6.5dbi gain off the sides, the loop would give you diddly-squat - RF mostly goes up. The higher the loop, the worse it gets actually.

I'm modelling a Halo style antenna right now which is half the size than a loop but a sort of omni-directional dipole.... Hang on and I'll send you the dimensions...

(Forget the halo - I'm getting a low impedance which you'd have to match to [15 ohms]. Dipole matches to Cox a lot easier!)

From: ash_lee52
Topic: 3186 Message: 4265

Have a look at the TW-2010 (www.twantennas.com) or the Force 12 Sigma 5 (www.force12inc.com) These are both about 10 feet high, work 20-10 meters and need no radials. Both are very high performance. I have both and prefer the TW-2010. See reviews for both on eHam in the portable and vertical sections.

4267. Re: 10 meter sky loop

Yahoo group: ham-antennas (2008)
Date: 2008-02-26 05:58:00 UTC
From: leonardo_da_vinci_nz
Topic: 4259 Message: 4267

I beg to differ. There are even a few Yahoo groups dedicated to the Skywire.

A horizontal loop can be a great performer but you want to make it at least one wavelength on the lowest band of operation. Then as the loop goes to multiple wavelength size you start to get lower angle. Not to forget that a (closed) loop has a lot less noise pickup, esp man-made.

If it is one wavelength then performance is about on par with a dipole as far as transmitting gain goes.

Never liked a vertical loop, neither these so called "interupted loops" which is actually a dipole folded into a square.

Marinus,

Disagree. The poster wants to build a 10m loop, fullstop - not a skywire(!) with a large diameter. IT WILL NOT WORK.

I am also a member of skyloops and the only reliable one I have seen is a 5 corner, 85 feet high version that projects fantastic rf DX lobes for 10m but it's over 400 feet long. I have two sky loops and they are only good for low bands because I can't get them very high.

For 10m DX, he needs a dipole or a yagi. A vertical may work for him too.

C.

I beg to differ. There are even a few Yahoo groups dedicated to the Skywire.

A horizontal loop can be a great performer but you want to make it at least one wavelength on the lowest band of operation. Then as the loop goes to multiple wavelength size you start to get lower angle. Not to forget that a (closed) loop has a lot less noise pickup, esp man-made.

If it is one wavelength then performance is about on par with a dipole as far as transmitting gain goes.

From: Roland Stiner
Topic: 565 Message: 4269

I am having some issues with high SWR with my G5RV on 17 meters. I am using the internal antenna tuner on the 756PROIII and it can't tune it down. The radio will work but the LED keeps flashing and then the auto tuner shuts off. My question is, what is the best length of coax to use so that the SWR will be lower on 17? I am currently using 75 feet. All other bands tune with the tuner. My G5RV has the 102' flat top and 31' of 450 ladder line.

17 is know as one of the problem bands for a G5RV. Adding coax will only trick the radio into thinking the SWR is lower as the coax loss will increase to attenuate the signal enough to appear as acceptable SWR. Since the 756 internal tuner is only rated for 3:1 SWR you could probably solve the issue by using an external tuner such as the LDG AT100.

Tricking the tuner would be good enough for me! I know
that when I had it at 50' I could get 17 but not 30, now
with 75' I gained 30 and lost 17. So where is the "sweet
spot" in the middle like 65'??? I put together some
jumpers (5' and 10') and will add them to the 50' to find
out this weekend. If I can shorten the coax that would be
great.

Yes, a vertical or a yagi would be best for 10m DX...
However, propagation is really terrible at the moment
and he is unlikely to make any DX contacts for some
months. His best bet would be using PSK-31 mode, but
even with PSK the chances of a 10m contact anywhere at
the moment are slim as anything.

This is a nice antenna design for operation from a fixed position. However, operation while moving is illegal in the US. The height limit above the road is 13'6". Besides getting the driver a fine, it can be dangerous as it can come in contact with electrical lines. It can damage telephone lines, cable TV lines and fiber optic lines. If the driver breaks a line that a business depends on, the person can be held libel for the loss of income for the down time. For example, it a gas station cannot make credit card transactions for two days you can be held libel for that amount.

On this last Christmas eve, a semi truck decided to use the county road past our house to avoid traffic. He apparently had a over height antenna because my phone and internet line were torn out. It was 4 days before service was restored.

If you run this on EZ-nec you will probably find that shortening the height above ground to 12 ft. will not reduce efficiency all that much.

The efficiency would be greatly improved if the coax shield were directly electrically connected to the vehicle roof.

Of course, if this antenna were mounted in such a way that it could fold down while traveling in an RV, it would make a great stationary antenna.

Could this be mounted on a bumber, therefore, lowering the base about 4' maybe? Would that decrease the effectivness by too much? And adding a "pivot point" wouldn't be all that hard to add.

1. Here is an interesting site I came across. It has interesting antenna links.

http://www.ac6v.com/antprojects.htm

2. Find any vintage of the ARRL antenna handbook. It will provide very useful information.

3. Any edition of the Radio Handbook by the late Bill Orr.

4. W4RNL http://www.cebik.com/radio.html

Also remember the following:

A. EH antennas are snake oil.
B. Isotrons are snake oil.
C. Any antenna that uses a resistor as a matching device is snake oil.

Snake oil? Depending on location, cc&r's, expectations, anything that radiates a signal will work. Even bedsprings, water pipes, or rain gutters. Yagis at 200 feet for some are just a dream. A good vertical at 20 feet will still work the world depending on conditions.

Hi Walt,
Thank you for your propmt reply to the point.
As you adivised,
AC6V,W4RNL,ARRL vintage handbook
and ARRL Hand book edited by Bill Orr OM W6SAI,
Every site or book has vast amount of antenna infomation.
I remember EH, Isotron, antenna with matching resistors
are snake oils.
I don't like a snakebite medicine.
How about an EH or a magnetic loop antenna which radiates very strong
magnetic field thinking it
exposures the neighbor apartment dwellers at living room?
EH or magnetic loop antenna is very useful but using in even 30W 30
minite on 10m or 40m SSB CW in the room or set it below the ceil some
friends experienced salivation or headache
dullness. The smaller or more convenient, the worse ....?
VY TNX GL OM Tim,

that put in the eBay sometimes,

Hi John,□@I have been concerned CC&R strengh, as a apartment dweller.
So I had tried EH antenna from Jack W0KPH? radiate 20W at 5m apart from
next dwellers' living room. Made Isotron on 30,20,17,10 and other
stealth antennas and they depends on the situation to install them.
But I had lived lower floor unfortunately when the boss command to
move me to be the dweller. So such a small, companct antenna is not
safe or even for 100 to 200W use, these were my experiences.
So I use FRP Glassfiber fishing rod stealthy expand them out at
midnight and collapse them just after a sunrise.
Dipole is dipole and long wire is long wire though
It is not snail oil. the closer to full size the better we could get
more entities. Snake or Zigzag radial on the restricted lanai has
something capacitive link to the construction.

From: Dan Schaaf
Topic: 4147 Message: 4288

Depends on the length of the antenna. If resonant and sufficient radials, no other tuning should be necessary. However, most people do not have the resources to install a full quarter wave vertical for 40 meters, so loading coils are installed to shorten the antenna. I have heard that top loading is best, but it also increases wind loading.

David,

(Your CAPS LOCK is stuck :)

You can just connect it directly with say a dipole centre. Make sure the "hot" centre goes up the radiating element and the shield goes to your radials. You can feed it directly assuming the following:

Feedpoint is 9 feet above ground

Radiating element is 10.1 meters long

2 x Radials are 10.1 meters long (I normally use 4 but honestly, for a tuned system, 2 will be sufficient)

Radials slope down to 3 feet above ground. Use nylon cord and tent pegs.

You will find that you will be extremely close to 1.5:1 across the band.

If you want this for the 7.2 to 7.3 section of the band, shorten everything to 10 meters and for final tuning, just fold back the radials an inch at a time until you get a perfect match. No need to take it down to change the vertical element.

That's the only design I know that will feed coax directly, see http://www.m0mcx.co.uk/?p=68

Regards,

Callum McCormick

What about the ground? I assume that you are going to have a vertical element around 32 ft 3 inches give or take. this would connect to the coax center.

drive a 10 ft. ground rod into the ground and then connect at least 4 10 ft radials to it. These can lay on the ground or be buried a couple of inches, whichever is practical. The coax shield will connect to the ground rod as well as the radials.

The more radials that you add, the better the performance.

With this design it is also possible to add a vertical element that is 1/4 wave for 20 meters.

The 40 meter vertical will be fairly close for 15 meters.

This is general information. Please tell us more about what you plan to do? Will the bottom end of the vertical be on the ground ? Will it be a metal element or wire ?

You can hang a 1/4 wave wire from a tree limb down to an stake with an insulator. Then place the ground described near the stake.You can add wires for different bands in parallel. Use 50 ohm coax.

A vertical will be better for DX than a dipole, but for distances under 800 miles, the dipole usually works better.

Please tell us more about what your goals are and your space requirements and trees or structures available.

I knew a tech back in the 70's that would sometimes say "K2VBK on the bedsprins.".
He actually loaded the bedsprings with his 6 meter Gonset Communicator.
He was living in 3rd floor apartment at the time. He tried a whip mounted on he fire escape rail outside his window, but he bedsprings actually worked better for the weekly AM net...
If tapped just right, and a way to get a reasonable match can be done, many things can work as an antenna.
I am lucky that my limitations are in what I have available to mount an antenna on.
I may mount my six meter beam on a 20 foot telescoping mast like I had it before. Could also use the beam to watch a few of the TV stations.
A tower would be nice, but the only tower I have is shortened (pipe top that was bent and would have eventually snapped at the wrong time), and will have my repeater antenna mounted on it.
And a tower can be loaded in some cases, a matter of having the right parts and tapping where it will work best.

BTW, there were some hidden mobile antennas made that were almost Snake Oil...
YMMV

There are a number of questions you need to answer before you start. How big a vertical? Quarter wave? Half wave? 5/8 wave? Short monopole (less than quarter wave)?

How high do you propose to place the base? Ground mount? Raised?

How do you propse to feed it? Base fed? Center-fed (half wave only)?

If ground mounted, how much room do you have for radials? If raised, what kind of counterpoise will it need and do you have the room for it?

The answers to these wuestions will have a major effecton how you design your vertical antenna. You might also want to consider how many nearby sources of vertically-polarized noise you might have to contend with on receive. Sometimes a separate receive antenna that is horizontal will hear DX better than your vertical, even though the vertical is great on transmit. Some serious DX buffs use beverage antennas for receive on the power bands.

In quiet locations, with a decent ground system, I've had excellent luck with verticals on 40m. One installation's first test resulted in a CW contact from VE1 to VK6 long path with two hours of daylight left!

C is clearly wrong. Many very cogent commercial and military HF installations have, for much of the history of radio, relied on terminated rhombics. Having used one on 60m CW myself many years ago, I have to say that they work very, very well.

The B&W broadband folded dipoles also work well above their "knee" frequency which is about where the length is a half wave.

It all depends how much of the transmitter's USEFUL (i.e. which would have been radiated in desirable directions without the resistor) gets absorbed in the termination.

In a properly designed terminated rhombic that can actually be negligible. In the B&W design it beomes reasonable above the knee frequency.

What ARE clearly snake oil are antennas that are simply very inefficient short radiators in parallel with a dummy load used to "match" them.

Hi gang,

Want a good, to the point, antenna handbook?

Saw this Marine Corp Field Antenna Handbook online. Lots of good info, and an interesting read.

http://www.armymars.net/ArmyMARS/Antennas/Resources/usmc-antenna-hb.pdf

Got a chuckle out of a few comments in it too.

"In an emergency, a ground connection can be made by forcing one or more bayonets into the soil."

and a couple of the warnings...

"EXCESSIVE SIGNAL STRENGTH MAY RESULT IN ENEMY INTERCEPT AND INTERFERENCE OR IN YOUR INTERFERENCE WITH ADJACENT FREQUENCIES."

maybe they had 75 meters in mind...

"THE WIRE MUST BE PROTECTED SO THAT MARINES DO NOT WALK INTO IT. IT CARRIES ENOUGH RF ENERGY DURING TRANSMISSION TO CAUSE SEVERE INJURIES."

It's in PDF format, so it's easy to save a copy. I found it full of good 'just the facts Ma'am' info.

No fluff, no opinions, just what works.

As you were..

Never could get the bed springs to load up on my old "Benton Harbor Lunch Box" on six meters, but using a bent pin to hook to the window screen got some fairly good contacts. (that was back in the G.O.D. (Good Old Days) when window screens were copper mesh.)

If the limbs of the tree are high enough, You can use wires for the element of the vertical. Drive a stake into the ground below the tree. Cut a wire for 1/4 wave length for the band desired. Install an insulator at the top and bottom of this wire. Connect the bottom insulator to the stake and a rope to the top insulator. Hoist the wire up into the tree with the rope. If you think that the wire is going to touch the tree limbs on the way up, use insulated wire. It is best if it does not but not a serious problem.

Next to the stake drive a 10 ft. ground rod into the ground. To the top of this ground rod connect 4 or more radial wires to the ground rod. These can be laid on top of the ground or placed a few inches below the ground to accommodate mowing. In time add more ground radials as the more the better.

The coax center connects to the wire, the shield connects to the ground rod radial system.

Several vertical wires can be attached to the same point at the bottom for multi band operation. It is best if they slope away from each other slightly as they go up so they are at least a couple of feet away from other wires at the top. The slight slope will not have much affect on the non-directional pattern. The same ground system can be used for all bands.

The 40 meter wire will usually work for 15 meters. Fix the support ropes so the wires can be raised or lowered for tuning the wires.

If there is not enough tree height for say, 80 meters, raise the wire as high as possible and bend the remaining end horizontal or even down at a angle to accommodate the remaining length.

If this is intended to stay up for more than a year, use UV resistant rope s for the final installation.

regarding support rope for the vertical antenna, i have been experimenting with an 80 meter horizontal dipole, about 136 feet long, with heavy rg 213 coax hanging unsupported from the center, and the entire system supported between two trees using .080 inch weed eater line. that plastic line is tough stuff, and handles the weight very well. just wear gloves while trying to pull up a lot of weight.

Sorry for the delay, I was out of town.

If you made it resonant for say 80m, it would fall more into the harmonics of other more common bands than having it resonant for roughly 60m. It would bring things to a better match on more bands.

Yeah if you have a very short coax jumper the losses are abated much more, so that isn't so bad.

I'm hardly an RF engineer, just got my call last April. I've just been doing a lot of research and tinkering, so take my advice with some salt too ;-).

4303. Vertical Antenna

Yahoo group: ham-antennas (2008)
Date: 2008-03-04 00:36:10 UTC
From: davidnapier2
Topic: 4303 Message: 4303

I want to give a big thank you to all that gave me their input concerning building a 40m.vertical and also trouble i had with hamstick,especially the following: Mike.Walt/N9WB-Dave Oldridge/VA7CZ-Callum McCormick,Dan Schaaf/K3ZXL-Mark/KJ7BS-Rick/N6NKN-Scott Gillis/N3UJJ,And any others i might have missed!! now i will assimulate this information and get busy building my antennas!!!!73's David Napier/KA4ZUC

4304. Telrex Model Identification

Yahoo group: ham-antennas (2008)
Date: 2008-03-04 10:04:25 UTC
From: comtinker
Topic: 4304 Message: 4304

Hello to all. I am new here, please look over my mistakes.
I have a sort of a problem trying to ID a beam antenna. I don't have all the specs at the moment but maybe someone will know without all of them. The antenna has the name of Telrex on it and it's a 3 element beam with a boom just shy of 10 feet. The elements do not go through the boom. They are held in place with what appears to be bolt together insulators, which is what has the Telrex name on it. The shortest element is around 15 foot with the longest element around 17 foot. Each element has what I assume to be some sort of matching attached to it in a sort of loop that is attached to the boom.
Can anyone identify this antenna?
Thanks

Would this by chance be a Telex KT-34 ?
See pictures at this link.

http://www.m2inc.com/products/kt/kt34/

If it is, it's a good antenna.

No, that antenna is built a lot heavier in my opinion. I appreciate
the help though. If I can get a camera I will try to get some pics.

Thanks,
Scott

4310. Tri-Band Vertical Descision

Yahoo group: ham-antennas (2008)
Date: 2008-03-04 14:54:54 UTC
From: James Thresher
Topic: 4310 Message: 4310

Hi everyone,

I'm in the process of designing my new VHF/UHF system but have one crucial decision left, which vertical tri-bander do I go for? I have narrowed it down to either the Diamond V-2000 or the Comet GP-15, the size and price is about the same and the manufacturers gain figures are very similar (If they are to be believed), I wonder if anyone has any experience of using both of these and can perhaps give me a real world comparison.

Thanks

73 de

James M3YOM

Google the company called PAR - they make an antenna called the ENDZ which is an End Fed Zep (not zeep) . There was an article recently in one of the Ham Magazines (QST I think) that spoke highly of them.

just outta curiosity ...

Has anyone ever build a short 80 meter vertical antenna ???
mine consists of
10' pc of pvc 1.5 inch dia sch 20 (2 inch od)
10' 1/2 " sch M copper pipe for top radiator
2 10' 1/2 pvc 90 deg to one another horizontal about 15 inches up from bottom of 1.5 inch pvc.
2 more pc 1/2" 10 long copper pipe vut into 4 pcs 5' long places in the end of the 1/2 inch pvc for end elements for GP

i have 34.2 ft of #14 THNN copper wire continously wound up 7.5 ft of the 1.5: pvc and soldered to the the 10 ' copper top element

and approx 22 ft on each of the 4 radials for ground plane and each attach to the gp end elements , and common connect the ground side of coax.

antenna is pretty good on 80 40 20 and hi side of 10 , but lacks tuneability on 17 15 and 12.

sig reports are approx 10 DB less between Fantail at 70 FT ele (132 ' dipole)
and GP on the ground at only 4 FT.

im curious if i did my cut and test method wrong to get the antenna semi resonant , and this is why i lack my high end HF bands ....

To add , i use a FT-100D and a MFJ 993B auto tuner.

4315. RE: [ham-antennas] Vertical Antenna

Yahoo group: ham-antennas (2008)
Date: 2008-03-04 20:59:43 UTC
From: Callum M0MCX
Topic: 4303 Message: 4315

Hello Russ,

James (M3YOM) and I have built collectively, three short verticals for 80m this year (we do a lot of experiments!). In our opinion, it□s the hardest vertical to build right - with loads of losses if you don□t achieve perfection. The first one we built was an elevated radial tuned system, delivering a near 50 ohm impedance with a shortened radiator of 12 meters (40 feet). And loading coil half way up (see the m0mcx website for pictures). Although we made the trip across the Atlantic to an N1 station, I□ve had much stronger copies on horizontal antennas. In fact last year in CQWW, I switched from Verticals to High dipoles (55 feet) whilst comparing antennas with a VK station and a number of Double-Yas. In both cases, they couldn□t tell the difference.

Currently James and I are both running vertical radiators of less than 12 meters with elevated radials. I have 9 radials between 5 meters and 12 meters in length and James is running slightly less, we are both having a serious 80m □get out□ issue. Last night, I had a sked with PA3A on 80m. He actually couldn□t hear me on the 80m vertical but I was 10db++ on my horizontal wire.

Bottom line is this: If you want a vertical for 80m, you will use up as much space (possibly more) than any horizontal wire and it possibly will only just achieve what the horizontal does now. More realistic is building a good vertical for 40m (in fact, both our verticals matched to the 40m band work fantastically).

Unless you can build these verticals "by the book" your losses may be too great. 30+ radials will be the key for a ground radial system (more really) or at least 4 x radials for elevated (James and I think more).

Dipoles at 40 feet sounds a great alternative :)

That could be it. The gentlemen I got this from said it was a 20 meter, but I cannot find any 20M antenna that comes close it's design. By the measurements I would guess it's closer to a 10M. If I could find someplace that has pics of these antennas I could probably identify it. I'll try to get some pics of the one I have eventually but still looking for the camera. I also forgot to mention that this antenna has NO traps, if that helps any.

Thanks,
Scott

id much rather use my quad band fan tail , how ever the dear friend im building this for has about 24' of back yard to intstall approx 5 ft above ground , so in all seriousness its gonna have to be the loaded elements vert GP . the community ok the installation of up to 24 ft " CB " antenna's but nothing bigger and not exceding 36ft in height .

i know i know , space restrictions are terrible to a ham , but i want to see if i can at least learn theroy on this design .

even if it is a lossy setup ...

I have 9 radials between 5 meters and 12 meters in length and James is running slightly less, we are both having a serious 80m "get out" issue. Last night, I had a sked with PA3A on 80m. He actually couldn't hear me on the 80m vertical but I was 10db++ on my horizontal wire.

Bottom line is this: If you want a vertical for 80m, you will use up as much space (possibly more) than any horizontal wire and it possibly will only just achieve what the horizontal does now. More realistic is building a good vertical for 40m (in fact, both our verticals matched to the 40m band work fantastically).

Unless you can build these verticals "by the book" your losses may be too great. 30+ radials will be the key for a ground radial system (more really) or at least 4 x radials for elevated (James and I think more).

Dipoles at 40 feet sounds a great alternative :)

just outta curiosity ...

Has anyone ever build a short 80 meter vertical antenna ???
mine consists of
10' pc of pvc 1.5 inch dia sch 20 (2 inch od)
10' 1/2 " sch M copper pipe for top radiator
2 10' 1/2 pvc 90 deg to one another horizontal about 15 inches up from bottom of 1.5 inch pvc.
2 more pc 1/2" 10 long copper pipe vut into 4 pcs 5' long places in the end of the 1/2 inch pvc for end elements for GP

i have 34.2 ft of #14 THNN copper wire continously wound up 7.5 ft of the 1.5: pvc and soldered to the the 10 ' copper top element

and approx 22 ft on each of the 4 radials for ground plane and each attach to the gp end elements , and common connect the ground side of coax.

antenna is pretty good on 80 40 20 and hi side of 10 , but lacks tuneability on 17 15 and 12.

sig reports are approx 10 DB less between Fantail at 70 FT ele (132 ' dipole)
and GP on the ground at only 4 FT.

im curious if i did my cut and test method wrong to get the antenna semi resonant , and this is why i lack my high end HF bands ....

To add , i use a FT-100D and a MFJ 993B auto tuner.

Subject: RE: [ham-antennas] Vertical Antenna

Hello Russ,

James (M3YOM) and I have built collectively, three short verticals for 80m this year (we do a lot of experiments!). In our opinion, it's the hardest vertical to build right - with loads of losses if you don't achieve perfection. The first one we built was an elevated radial tuned system, delivering a near 50 ohm impedance with a shortened radiator of 12 meters (40 feet). And loading coil half way up (see the m0mcx website for pictures). Although we made the trip across the Atlantic to an N1 station, I've had much stronger copies on horizontal antennas. In fact last year in CQWW, I switched from Verticals to High dipoles (55 feet) whilst comparing antennas with a VK station and a number of Double-Yas. In both cases, they couldn't tell the difference.

Currently James and I are both running vertical radiators of less than 12 meters with elevated radials. I have 9 radials between 5 meters and 12 meters in length and James is running slightly less, we are both having a serious 80m "get out" issue. Last night, I had a sked with PA3A on 80m. He actually couldn't hear me on the 80m vertical but I was 10db++ on my horizontal wire.

4320. My Antenna

Yahoo group: ham-antennas (2008)
Date: 2008-03-05 05:51:06 UTC
From: ke4vyn
Topic: 4320 Message: 4320

My system for opinions and critique.

I live on a slight hillside so my doublet's high side is 40 foot high
and the low side is 75 feet high.

Its feed with a 450 ohm ladder line that hangs down 35 feet. I have
a coax air choke as it enters my shack. Its tuned with a Ameritron
ATR-15. Feed with a Icom -718.

The 134 foot #6 wire runs NW to SE. I wanted to run 160m so I added
60 feet of #12 on the ends and since I'm outa real estate the
NW 'end' runs downward and north.

The other end is more vertical and is pointed south.

The numbers are at 3 Mhz the SWR (lowest) is 2.3 with R=33 and Xc=32.
and the total run is now 254 feet.

Any thoughts?

Lee

4323. VHF/UHF base station antenna

Yahoo group: ham-antennas (2008)
Date: 2008-03-06 01:17:53 UTC
From: Earl
Topic: 4323 Message: 4323

Hi Everyone,

This is my first post; I'm planning a modest (in scale and $) base station antenna for VHF/UHF voice and for APRS (weather). I'm a bit confused as to what sort of antenna and the location.

I thought of a discone but have read that a dual-band stick would give me better performance. I figured I would mount the antenna off a chimney mast. A stick has no ground-plane, so I'd have to get a model which can work this way. And, in general, most VHF antennas shouldn't be mounted high for proper low-angle radiation.

I have a second-floor wooden deck but didn't want to run a mast off the deck's side because of aesthetics. I live in a bi-level home so my chimney is only ~ 20 ft (if that) above ground. Finally, I live in a well-populated, though low-lying area. My cell service isn't very good, just to give an idea.

I've thought myself into a corner - any thoughts?

many thanks in advance.

Earl,

You are going to be line of sight because of those bands so what you are probably going to have the most success with is hitting repeaters. I am going to assume you have explored repeaters in your area and are aware of ones in you ~should~ be able to reach. With this in mind, I would suggest an Arrow Antenna J-pole. If you want to explorer out further and can work with stiff directionality, I suggest looking at and Elk Log Periodic.

The J-pole is pretty cheap and real easy to put up. I stick mine on a piece of 1 1/4" mast and dropped the mast part way down a drain vent on the roof. I put a U-bolt around it at about 3' from the bottom to keep it from dropping all the way into the vent pipe.

For an Omni dual band.. I suggest the Cushcraft AR270B. A real metal antenna (not fiberglass with a wire inside) with decent gain for 119 bucks at most vendors.

If your want directionality.. get individual beams you'll benefit from greater gain and front to back ratio.

For an omni go with a dual band.. and use it for a Rx antenna when you transition to Yagi's.

If you want a commercial tri bander look at the Diamond X3200A or the Comet CX333. Both will give you good gain on all three bands but they are about 10' high.

If you drop to only a dual bander a Diamond X30A, Diamond X50A, Comet GP1 and Comet GP3 are all good choice at only around 4-5' tall. Also the Arrow J-pole in single or dual band would be another good choice.

You could also make your own 2m J-pole antenna. The 2M J-pole will load up on 440 but doesn't have the best radiation pattern. You could also build a j-pole for 220 if you used one of the commercial dual bands.

All of these options should give you pretty good range when mounted on top of your chimney. All these options don't require ground coupling to work well.

That would be true, however ground coupling is a great thing.. I have seen all too many top mounted fiberglass antennas end up thousands of shards in your lawn.. The first discharge takes out the wire antenna in the tube, the next charge tries to go to ground (ungrounded antenna) and cant unless it uses your coax to get there.

I do have a comet as a repeater antenna, 300 ft on a 476 ft tower but never as a top mounted antenna. Too risky..and not rugged enough.

Ground coupling for RF Ground is not required for operation of those antennas. Ground path for lightening protection is a totally different thing and I agree you need to address that or your radio can become the ground path.

Personally, I got a Diamond X50A. Was $99.95 at HRO*. Since they offered free shipping on orders over $100.00, I had to add a $1.00 item (cigarette plug for me) and avoided the $7.00 "small order" fee and to qualify for FREE shipping. I priced these at about 5-6 places, and HRO was the cheapest delivered. $109.94 CONUS.

Band/Gain = 2m/70cm @ 4.5dB/7.2dB and 5' 6" tall. Would mount well to the chimney.

Nothing wrong with the others either, I just chose the Diamond, and the dualband since we have no 220 repeaters in my area. Comet is about the same price (plus/minus a buck or two) and both the GP3 and the Diamond X50A have identical gain and max power rating. Comet GP3 is 5" taller at 5' 11".

* (I have no affiliation with HRO...I just always shop around for they had the best price on this item)

Steve, NS5B

Taken from the Universal radio online catalog

Cushcraft AR270B 144-148/430-450 MHz 5.5/7.5 dB 7.7 ft. (2.3m)
$119.95

Diamond X-50 2M/440 4.5/7.2 dB 5.6 feet $99.95

Spend the extra 20 bucks and buy a metal antenna!

Just another .02 to chew on.

I just recently put up a dual-band vertical and decided to just get a serious antenna and be done with it.

I put up a Diamond X510, for masting I simply used two ten foot sections of hurricane fence top-rail for about $10 each length. I drilled and sheet metal screwed them at the joint and it's quite strong.

I attached this to the end of my house using gable brackets to hold the rail in two places. The top bracket is just at the joint of the two pieces so it gives me about ten feet above the peak of my roof for elevation.

The performance of the antenna has been fantastic. I ran 9913 low loss line for the feed as well, don't cut corners there, go with at least 9913 or better yet LMR-400. You want to minimize losses wherever possible or the antenna you connect to won't do anything for you.

It wasn't the cheapest configuration, but I'm learning that getting an installation done well and done properly the first time is much more satisfying. This should be in the air for many years before I have any trouble with it and it performs great.

As far as being visible, I find that a simple vertical like this is really not that noticeable. It may seem huge at first, but really it doesn't have the visual impact of a big tri-bander yagi by contrast. You'll be more frustrated I think if you put up an antenna and realize that you could have that 'just a bit more' to help snag the signals.

The Arrow J-pole does work well and will get you to all your local repeaters nicely, but if you like playing with simplex at all, go for something with more gain, you won't be sorry.

I think metal antennas will resonate over a wider bandwidth than a relatively thinner element in a fibreglass radome. Metal feels nicer on the skin too.

Chris.

All this in my maybe not so humble opionon:

Most always they are more broad banded. That is to say that the operational curve when VSWR's are graphed is much wider..
Unless your talking about something like a motorized antenna such as a STEPPIR.

Usually fiberglass antennas are not a "Grounded" antenna.

Usually they resist much greater winds.

Most times they are lighter.

Much less susceptible to static discharge damage (lightning).

When they are hit by lightning the metal antennas are much easier to pick up in the yard!

AE5MH

I have seen warnings about putting an antenna on a chimney. They aren't strong. In a storm, the antenna could bring the chimney down.

> And, in general, most VHF antennas shouldn't
> be mounted high for proper low-angle radiation.

Not sure what you meant by that?

We aren't talking high like 500'.

If your cell service is poor because your area is low, it is likely that higher is better and will give you more coverage.

Andy

Sounds like a Telrex 3-element 10 meter yagi. They used to be
famous for their very effective and sturdy beam antennas. W2HCW
used to dominate the North Atlantic path with a 3-element 80
meter beam they made for him. Of course his location helped,
too, along with a good amplifier, but he could also hear well...

As far as I know, the company is defunct now. But if the beam is
in good shape, it ought to be usable. Many of their antennas are
still in service.

questions for you and ideas

Are there trees close to your house?
If so, At night ;) string up a long wire antenna through the trees. Wire should be at least 100 feet (The G5RV is 102 across the top)

Or string up a dipole between trees.

Get an antenna tuner and hook the wire antenna into the tuner.

Just a note. Having an antenna in my neighborhood is not prohibited and I could even set up a tower with a Yaggi on the top if I wanted to. I chose to put up a dipole through the trees on my property. I have a homebrew dipole though it is 68 feet of 14Ga copper wire for the top sections and a 31 foot ladderline feeder to a Balun. Total 136 foot with 31 foot ladder line. 80 meter dipole I guess is what the true term is but I have great results on all bands. I use a tuner to get the ant. set right.

hope this helps you.

Brian - KC9FACV

The question was for a RECEIVER. A G5RV antenna is not needed as well as an Auto Tuner will not work at all as it needs Transmit Power to tune it.
Just get a ground on the receiver and as long a wire as you can get hooked to the antenna terminal.. It needs not to be tuned as your good receiver will take care of that ... Do not mess with coax just run the wire direct to the radio.
Remember.... Longer is better....

Actually, a tuner can amke a lot of difference with receiving. But it is
easier to use a manual tuner, just adjust for maximum noise or signal.
The instructions for my older manual MFJ tuner suggested starting that
way before adjusting for lower VSWR....
However, as you say, it is not essential. I never heard of a receiver
going bad from using a poorly matched antenna. But used righty, a tuner
can help reception...
Auto tuners can, in some anyway, be manually adjusted.

Back in the 50's, I simply used an end fed wire as an antenna to receive
a great amount of short wave broadcast and such...
YMMV

hi fellow hams,
I just purchased a used cushcraft r8. as i assemble
it i am checking continuity. i notice that i am not
getting continuity from the center pin on the so239
input on the matching network to the antenna itself.
is this the normal design of the antenna or do i have
an open connection somewhere?
thanks in advance paul w8jn

Robert which model receiver do you have? The reason I ask is even my old Realistic DX-160 has a dial for "Antenna Trim", this is virtually a built in "Tuner" that matches the radio to any wire you attach to it for better reception. For outdoors longer-higher-and bigger is always better, but a number of indoor antennas can give you plenty of signals to listen to. I've used "Active Antennas" as was suggested earlier by gadzooks mike, various loops etc. Is your apartment on the first floor or? Is there any attic space above your apartment?

If you're above the first floor it would be better but it will also work on first floor is to run a very thin wire along the top of your baseboards to connect your radio to. For maximum invisibility it could be something as small as 24-28 gauge magnet wire, but I would use something at the connection end that could mounted to the baseboard or wall to keep from breaking the wire when connecting-disconnecting or moving the radio. Maybe a 1/8" phone jack connected only on the center pin so it would virtually be a longwire antenna. The just make a adapter for the radio connection whether the input is a SO-239 or screws for wires on the radio end and a 1/8" phone plug to connect to the jack on the wall you made. GROUNDING the radio makes a BIG DIFFERENCE in the quality of your reception as well.

If you do decided to go the mobile antenna route any, including a simple 102" CB whip will work, but again quality of reception will suffer and with so many possibilities that cost little to nothing you can build.. it's not worth it.

Sam

Hi Doug,
I am very appreciated to see over 190 pages shown very much field tactic telecommunication antennas and their installations the RF must reach to the object correctly in band, how to installe, etc, though I saw this pdf at all now.

> "In an emergency, a ground connection can be made by forcing one or
> more bayonets into the soil."

Looking many installation cases, there is just a byonet in the ground is curious.is it enough to us amateur drive RF to DX?
Just putting bayonets in the soil except interference issues, Is it okay for HF bands?

> and a couple of the warnings...
>
> "EXCESSIVE SIGNAL STRENGTH MAY RESULT IN ENEMY INTERCEPT AND
> INTERFERENCE OR IN YOUR INTERFERENCE WITH ADJACENT FREQUENCIES."

I know ERP may be very important at the point to protect the enemy intercept,
> maybe they had 75 meters in mind...

hello, all. I'm a new member to this forum. You know, Sam, if you live in an upper floor apartment, there is no reason why you can't "top feed" a wire suspended over the balcony railing. Many hams have a small fishing reel with thin wire and a weight at the end. Unreel it down for listening session. After unreeling to a good length, clip a wire at the top (reel end) that goes over to your radio. When done,unhook and reel it up. End-fed antennas don't care which end! Less critical for SWL Vs transmitting.
Respectfully,
Phil

I think you may be right. I did get a camera and will try to figure out how to post a few pics when I get a chance and the weather permits. I do not have the antenna assembled but hopefully someone can identify it from the parts. The element isolation brackets that are used look unique to me but then again this is the first Telrex I have seen.

Thanks

That's a possibility as well, but I have no idea which floor Robert lives on, it was his post I was answering. In his original post he also said that no wire antennas were allowed at his complex which is why I was trying to give him other ideas. Using the method you suggest would/should be fine after dark, when nobody is around but then you'd miss out on the bands that are active only during daylight hours so you'd still need another antenna to enjoy those.

The FCC says 200' structure.. The reason for that is that over 200' requires either a day stobe or red/white paint, and has to be night red beaconed. Oh yeah and registration with the FCC with the registration number posted.

Over 200' is not considered amateur operations.
The lighting over 200' is an FAA requirement.

4359. Dipole on my fence

Yahoo group: ham-antennas (2008)
Date: 2008-03-09 05:34:20 UTC
From: pitbon
Topic: 4359 Message: 4359

Due to my HOA restrictions i want to try a dipole on my split rail fence.
Anyone tried this and had success?

The only thing im worried about is the feed line touching the
ground...is that a problem? I thought i had read that somewhere.

My fence is about 4 foot high but because of my lot lay out, the fence
in my back yard is about 20 foot higher than my ground floor level of
my home.
Can I just lay the feed line on the ground or what does anyone
suggest? Im of course trying to be stealthy with the whole thing so
any suggestions would be GREATLY appreciated!

Bonner KJ4BKK

Bonner,

Contact Sherman, WA6TVS, I think he has his Cobra Ultralite running along a fence. I can tell you from talking to him that it works great.

I think you will find the 200 ft FAA rule in all the land. And if
you are close to an airport. and that goes out for miles,
restrictions are lower. Some as low as 70 feet or less.
Then you get into County and City restrictions. Permits, Boards for
zoning variances. Every group has a say in your tower.
I was turned down at one location because the locals thought it would
kill the birds.
But they still want there phones to work every where they wander.
Even hams must look out for zoning of towers. Some governing bodies
think a tower will fall straight over and not crumple if it falls...
So you must have more space around your tower than it is tall..
Sure nice to be retired...

There is a method where an antenna is mounted very low to the ground,on the order of several feet I think. The method is referred to as a "cloud warmer" due to it's very high (almost up) radiation angle. End feds,dipoles, and more comminly low band loop antennas are used.
Here is a url link to one of the designs.

From: Brian Erwin
Topic: 4359 Message: 4364

When I was getting started in HF I had the rig and a long wire antenna. It worked pretty well and I was able to tune it to almost any band.

I have no restrictions in my neighborhood and I am pretty good with that but I wanted to be stealthy because I was in a new house and I didn't want to start a frenzy on my block.

I took this long wire antenna and shot a line up into the tree in the back yard and pulled one
end through the tree. I did this a couple of other times and got part of the Antenna to stay up in the tree.

My next door neighbor had a wooden fence and when he put it up made sure that the good side was on the inside and the construction side was was facing out.

My advantage was to run the wire from the tree to the fence and staple it to the long boards along the top of "his fence". He was not able to see it because he had the pretty side
to look at.

By using a tuner I was able to get all bands and work coast to coast.

Now I use a diploe strung up in my trees!

I meant to mention that with these "cloud warmers" usually a wire counterpoise is ran on the ground directly beneath the radiating wire. Really, all an antenna is supposed to do is radiate energy. I've heard of hams talking from their dummy loads (unintended). Hams will always get on the air!
Best,
Phil

I've heard of 160 meter listening antennas buried. Really cuts out the static. Usually the transmitting antenna is some sort of a shunt fed tower.

Bonner,

Your feedline can lay on the ground so long as it is coax. Open wire line will experience a lot of loss if laid on the ground or buried. As for the antenna, such low antenna will be a "local" antenna at best a few hundred miles as a dipole that close to the ground is an NVIS "Near Vertical Incident Skywave" where most if not all of your signal goes up instead of out. These make great antennas for geographical communications like during a disaster where you want to communicate with teams in the immediate or near immediate area.

Think about an end-fed wire antenna. If you make it/them out of small gauge wire, say 26 ga, nobody will be able to see it unless very close to the antenna.

Another alternative is the PAC-12 portable antenna. This antenna is designed for backpacking and portable use. I have one I use a lot. It is not a stacked set of beams but does quite well. This is a short vertical with radials and stands 10 - 12 feet tall. One option for this antenna is a coil that allows you to adjust the resonate frequency from 10 to 40 meters. The antenna easily handles 100w and I've made contact with Japan, Brazil, Alasks, Hawaii on it this far in 2008. http://www.pacificantenna.com/

Subject: [ham-antennas] Dipole on my fence

Due to my HOA restrictions i want to try a dipole on my split rail fence. Anyone tried this and had success?

The only thing im worried about is the feed line touching the ground...is that a problem? I thought i had read that somewhere.

My fence is about 4 foot high but because of my lot lay out, the fence in my back yard is about 20 foot higher than my ground floor level of my home.
Can I just lay the feed line on the ground or what does anyone suggest? Im of course trying to be stealthy with the whole thing so any suggestions would be GREATLY appreciated!

> hello, all. I'm a new member to this forum. You know, Sam, if you
live in an upper floor apartment, there is no reason why you
can't "top feed" a wire suspended over the balcony railing. Many hams
have a small fishing reel with thin wire and a weight at the end.
Unreel it down for listening session. After unreeling to a good
length, clip a wire at the top (reel end) that goes over to your
radio. When done,unhook and reel it up. End-fed antennas don't care
which end! Less critical for SWL Vs transmitting.

HI all,

I have the same king of dilema as Sam. Having considerded the
fishing rod senario, it seems relative simple to bring in your
antenna each time.

Also, an anttena such as this will not be as noticeable as a permanet
type.

Speaking of killing birds, I have evidently whacked a few with the two
meter magnet mount on my vehicle. Nice loud twang at 70 MPH....
regarding airports, there used to be a spec of only so many feet for each
so many feet from a runway, Got higher as you got farther away.
The information as I recallw an in the amateur handbook way back. Look
through one from the 50's or 60's, should be in there if I am not mistaken.
I would love to have a tower like they have at the fire station here,
nice tall, heavy wand well guyed. Looks to have 5 or 6 antennas on it,
including a loop dipole array...
I'm not sure how hight it is, but no lights on it, at east not that I
saw, while the cell phone tower north of town has strobe for day and
flashing red for night, so must be below the requirement for lights...
Looks to be at least 90 to 100 feet tall.

The way you find out is to go to the city. They will have this
drawing with all the distance and hight requirements on it.. If the
tower is on the side it can be higher than if it is off the end of
the runway. Also it depends on what kind of instrument landing
system they have or not. And even if you are still under the
drawings height the FAA office for your area can tell you what else
you must do... Lights or strobes or if it must be painted.
I have even ran into a blockage from a filing the local airport did
years ago for a second runway crossing the main runway.. As far as
the FAA was concerned it was in force...
Also... If you are near an AM radio station you may have to do some
Very Expensive work to replace the AM pattern of radiation. This can
be needed even if you are MILES away from the stations tower...
Everyone is Right and you are in the Wrong..

4373. 144/440 antenna for a window

Yahoo group: ham-antennas (2008)
Date: 2008-03-11 03:01:57 UTC
From: John
Topic: 4373 Message: 4373

First off I am new to the group, so hi to all.
Now I am trying to get my uncle back on the air. He is 90 an has moved into a an assisted living trailer park. Can you believe it they can't put up any kind of antenna. (In a trailer park, go figure)
I managed to put up a wire for his HF, but the repeater work is not so easy. I remember someone making a dual band out of alarm tape on a window. Does anyone know how to do this? I tried to put him an antenna inside but it was hit and miss at best.

How about a mag mount dual band on a tool box? Works for me. Does he have a vent he could use? I have not tried the vhf/uhf antenna but the HFp is great. Its an antenna that slides over a vent. It also has good reviews. www.ventenna.com I hope that helps.

All Great ideas, but again it is a mobile home made of metal with metal blinds. I cannot put anything outside that looks like an antenna. The only thing I can think of is alarm tape on a window or something like that. He has an HT but the repeaters are about 15 miles away and the metal od the mobile home is blocking the signal. Outside it works like a charm. I tried to make one but the SWR was 5.1+ so I know I did something wrong.

How abt a mobile HT antenna? They are so small and thin perhaps nobody would see it. Put it on the middle of the roof and for sure no one would see it.

OK- A "work-around" here... Have you seen those flags everyone mounts on the front of their homes? The mast is usually 3-4 feet long,and slips into a wall mounted bracket that suspends the flag on an angle. Usually about head-high,and there are colorful flags to interchange for the seasons. Very commonly used. There is a J-pole antenna project using either 300 ohm or 450 ohm transmission line. This can be slipped into the PVC pipe with a cap on top,and a descrete exit hole at bottom for RG-58U coax. Usually these are 2 mtrs, but I thinh they can be made dual band 144/440. I will look it up and send link. This solves your problm: it's outside, high enough,and is a flag pole.
Best,
Phil

Get some 1 to 1 1/2 inch pvc pipe.. Make it into a nice
flag pole... put your antenna inside the pipe and
mount it to the side of your home.
Fly the flag a lot.... hi hi

John,

How about a 2 meter j-pole antenna, check this site
<http://www.kb3kai.com/j-pole.php>
they have a picture of a field-deployed J-Pole
hanging from a tree and it is hard to see. Or hang it from a porch
roof. If there is a tree in the yard near the trailer you could
attach it with fishing line and run the coax to the trailer, just be
careful when you cut the lawn. HI,HI
And the antenna should not cost much to make.

PVC and J-Poles made from Twin-Lead mounted inside the PVC make good companions for stealth operations. Does he have a SHED outdoors next to his trailer? What is that made of? Metal or Wood? If wood mount the antennas inside of there. If not.. can he have a shed? Lots of fairly cheap ones made from wood and plastic that would make a nice hiding place. The don't have to be big either.

Two ideas come to mind one is put an old style am antenna
on the vertical but use a 5/8 wave 144mhz or dual band
whip and matching network at the base.

The other is 10 to 12 years ago a friend won as a door prize
a folding square dual band loop made by some company in
Germany, outer square element was 144 mhz
the inner square loop was 440 mhz was in the corner by the
feet, it was designed to fold up like an old carpenters wooden
rule.
The feed was in the corner and could be set in a window
polarization change was possible with how the
thing was hung in the window, not sure if coax was supplied or if
the length was part of the antenna network for tuning or what
connector was used probably bnc I just don't remember.

Back in the late 60's I worked at Cadillac there was a
mechanic who was changing the power antenna am/fm
radio antenna to work low power on 11 meters, later
some Cadillac cars even came with am/fm cb radios
I would think the same power antenna could be configured
to work 144/440 mhz

I have used a Ventenna disguised VHF antenna for a few years. My son-in-law used it on Tyndall AFB for three years as he didn't want to go thru the hassle of getting persmission from the Base Commander, Civil Engineers, God, and who knows whom else.....it works great on VHF. I am unsure as to wheter or not they have a dual band or a UHF model, but if it is good 'nuff for the CIA, DIA, NSA, and a couple other three letter organizations that do clandestine work, I think it will work pretty well for us.

Do a google on "Ventenna" and check them out.

hi john,

take a look at this antenna, called half square for 2m,
direct fed 50 ohm coax, you can hang it in front of the
window inside or outside the trailer.

http://www.cebik.com/vhf/hs.html

you can use white (or other color #12 thhn solid wire)
wire to match the color of the trailer.

or hang it inside behind the window shade, nobody will
ever see it and your uncle will be able to get on the repeaters.

My 5th wheel has an attached, exterior radio antenna
that could be replaced. Mine also has a crank upTV
antenna that I could attached to. A wire J Pole out
the window . .

Copper J Pole with plastic propellers and paint like a
art/craft project?? Anything hung as a decoration . .
vertically or horizontally. Decorative umbrella could
be a ground plane . .

Flag pole . . aluminum . . or wood with wire grooved
in and
feed under a mat?

My personal choice would be taking whatever you have
made work and disguise it with decorations so it
simply looks like something else. I would look for
some decoration type I had seen within the park . . .
stands with flower pots . . awnings with decorations
hangings . .

A potted rose bush . . What if you put appropriate
length
dipoles . . maybe stretched out on a one by six so you
could put that up on his roof. It could be outside
the aluminum skin but maybe only 4, 6, or 8 inches
high so not to be visible from the ground. Black
disappears . . black board . . black wire . . thin . .
The Wireman has this incredibly
strong black wire he markets as invisible . . and it
is.

Richard
WB6LUJ

Now I am trying to get my uncle back on the air. He is
90 an has moved into a an assisted living trailer
park.

Never miss a thing. Make Yahoo your home page.

I have the Dual band Ventenna. Works ok on UHF. Gain is not very high
but given it or having to use a indoor antenna there is no comparison.

A very good antenna for this is a lazy-H configuration, basically two double-zepp antennas in phase. Make it 76x38m and put it 10m up and, over normal ground, it will project a strong overhead lobe on 75m. It will be quite strong out to about 250 miles, then fall off by more than 10db as distance increases to 600 miles. After that it falls off very rapidly. The antenna should have good rejection for low-angle noise, both locally-generated QRM from non-radio devices and distant thunderstorm QRN from storms outside the footprint.

Of course it's large and the price of gain is real estate.

4395. new ocf dipole

Yahoo group: ham-antennas (2008)
Date: 2008-03-12 12:56:40 UTC
From: Bill
Topic: 4395 Message: 4395

Made an ocf dipole based on the one in the ARRL antenna book. Just slapped it together and figured I'd trim it after getting it in place. I pulled it up on a very temporary mast to about 15ft at the feedpoint. Got a match on all but 75m, but the low end of 80m was good. Measured more precise and folded back the ends to what was given in the book, and it got a little better, but still had to improve. Added about 250pf in series with the long leg and now I'm good up to 3900kHz. I saw one design that used 470pf, so that's next. This weekend I hope to make a good mast that will get me up to about 35ft. That's just over roof height, so I think the xyl will not complain too much. It's almost flat on 40m and 20m. I was told I was 20 over in VA from NY with a barefoot IC-735 on 75m. I think the biggest hurdle I had to get over was the idea of end-fed, carried over from swl days. I had one fed through a xfmr I made and got a match from 80 up through 17, but I don't know how efficient it was. But I did talk into europe, through pileups, on 20m a couple of times.

I'm having lots of fun!

A couple of places, hamwaves.com is a good source. Also K3MT, seems like a couple more. The only thing to make sure of: standard ceramic or mica caps in the right voltage rating can handle the current of a couple hundred watts or so, but not full power, due to lead size. One thing I did was take 4 ceramics I got to experiment with and tied them all in parallel. The values add, the voltage rating stays the same, but the current is distributed over multiple wires(leads) instead of one tiny little lead. For full power it's recommended to use doorknob type high voltage caps.

What a Gestapo!
Older folks have so few joys,ask so little and ham radio is one that anyone can enjoy. Then they better remove all microwave ovens (radiation) Tv's (high voltage Xray) florescent tubes (mercury) and table wine. And anything colorful,or happy. Might choke.
Sorry. That pushes my buttons. God Bless you for taking him from that atmosphere. You just don't know . He really appreciates your heart. You and your wife are honoring him with more decency than some do their parents. Hope it all gets ironed out.

Man, that sucks! It absolutely amazes me how society and those that care for older folks treat them! I am furious. Our nations senior citizens are limited it what they can do, and to take away a 2M radio because of some stupid rule is ridiculous. Danger to the park and it's residents - what a bunch of crapola THAT is.

I commend you and your wife for taking him in - kudos for you. The nurse needs to be tarred and feathered. Maybe get a big vat for management too. How absurd.

Tell your uncle I said *hi*.

John,

Sorry to hear about the problems with 2M for your dad. Personal Care (?) homes are a sham. We took my wife's aging Aunt Betty in with us about 9 years ago. She is mildly retarded but at 76 years old (last Feb 5th) she has more on the ball than most of the nurses at the center she was at! We didn't like the conditions or the lack of supervision (1 nurse for 40 patients), etc.

God Bless you and your wife for stepping up to the plate.

My wife, Patricia, KB3MCT, and I both have seriously considered trying to find some financial backing for a facility that catered to elderly ham radio operators. Put several towers up on the roof, a set of all band dipoles, and presto: you have a octogenarian contest group!!

Seriously, I would love to see a facility that would allow radio antennas, even modest ones.

John,

As a RN and Ham...I am sorry he was turned in by his nurse. The nurse should have known better that the radios were needed for his mental R+R and his overall health and spirits. You should let that nurse know what he/she did and what the radios meant too him. I would write a letter to her/him. The radios should been ignored....sorry this happened to him...

John,

Sorry to hear about the problems with 2M for your dad. Personal Care (?) homes are a sham. We took my wife's aging Aunt Betty in with us about 9 years ago. She is mildly retarded but at 76 years old (last Feb 5th) she has more on the ball than most of the nurses at the center she was at! We didn't like the conditions or the lack of supervision (1 nurse for 40 patients), etc.

God Bless you and your wife for stepping up to the plate.

My wife, Patricia, KB3MCT, and I both have seriously considered trying to find some financial backing for a facility that catered to elderly ham radio operators. Put several towers up on the roof, a set of all band dipoles, and presto: you have a octogenarian contest group!!

Seriously, I would love to see a facility that would allow radio antennas, even modest ones.

Talk to your local newspaper or TV station- contact the ARRL and get them to say how safe radio is. Drag up his illustrious past as a war hero etc etc.

They'll cave in!

Steve G0KYA (UK - where we aren't quite so daft, but are getting there)

Now that is an excellent idea. Even though you and your wife took your Uncle into your home, I think the local TV stations would have a field day with a story about what happened to him. Get the ARRL involved as suggested, or at least call them to find out what could be done. Perhaps local ham clubs could be interviewed as well.

Btw, what's the name of the facility?

4412. Detuning antenna?

Yahoo group: ham-antennas (2008)
Date: 2008-03-13 15:01:34 UTC
From: Melvin
Topic: 4412 Message: 4412

I have just put up a fullwave delta loop for 40 meters. I used a 4:1 balun and coax to feed it. Without my internal tuner the swr is great across the entire 40 (and also 15) meter band. When I use my tuner (I know, why would you do that if your swr is great) it has a problem tuning the antenna. I was just wondering if my tuner might have a problem or is it maybe detuning the antenna.
This is the first loop I have put up since having this antenna (FT450).

Thanks,

Melvin, AB5EQ

Hello Melvin,

I've been a bit of a full-wave loop freak for a couple of years and my 40m dedicated loop is fed like yours. I also get a great result on 20m too. Is yours horizontal or vertical?

I've never had a problem with the tuner on the loop, but I have heard that if the impedance is too close to ideal, the CPU in the internal tuner can throw a wobbly because the antenna isn't too far away from being a good match so it gives up. That's my theory anyway!!

(By the way, I've just designed a 2 element vertically polarised switchable delta loop that gives 3.6dbi gain at 10 degrees elevation - I shall be trying this next month at our next antenna-fest. Has anyone ever built one of these..?)

Cheers,

Callum McCormick

Tell me: If you leave your tuner in circuit,but switch it to "bypass", another words it's in line but the tuning is not, how is your match? I wonder if just the extra line length and the box,etc has the effect.

I have the FT 450 and I change the setting from internal ATU to external atu, so I suppose its not in circuit.

Thanks for the reply

4417. 20m dipole

Yahoo group: ham-antennas (2008)
Date: 2008-03-14 15:35:14 UTC
From: Kenny Wyss
Topic: 4417 Message: 4417

Just wanted to see if anyone could make any recommendations on my next antenna build for 20m. I have been running a G5RV for over a year now, and have had excellent results, even working the DX pileups with only 100 watts. Have worked the world on that puppy. I would think that a properly tuned 20m dipole would even be better, so I was thinking of making one. Should I go halfwave or fullwave? Anyone have any great results on 20 with anything they'd like to recommend?

Thanks and 73,

Kenny, KB0NPW

80m full wave loop would be my suggestion to try. Or more exactly, make it 4 full wavelengths at 20m so it is optimized for it. You would see some decent gain from that.

If you feed it with open wire or window line and use a manual tuner, you will minimize losses on a major scale, and it could be tuned from easily 80m and up that way as well.

Others to look at, a 'double bazooka' which is basically a collinear wire antenna, again has some gain.

Or if you really want to get fancy, look into a Lazy-H though if I recall that will be bidirectional so you have to position it to point where you mostly work.

http://www.cebik.com will have info on the Lazy-H and HOPL's (horizontally polarized loops) to read about.

Here in Hampton Roads, Va we have a Ham in his 70s. He is bed ridden in a nursing home run by Sentra Hospital system . They have no problems with his hobby. Some of the members of the Chesapeake Amateur Radio Service W4CAR got together and set him up with a pair of HTs a simple ground plane (SP?) vertical antenna and a J-Pole. With these antennas he is able to work all the numerous repeaters in the area except one, on low - med pwr. If Al did not have that he would be reduced to staring at 4 walls taking pills, shots, and meals and not very much else. With the friends he has made he has plenty of visitors. I'm glad to call him my friend. Is ham radio good for shut ins? You bet!

Hello to the group. I just bought a vhf una pole antenna. Question is, How well will it work as a simplex repeater antenna. On the freq that I will be using, the swr is 1.4 to 1 @ about 80 ohms. Your thoughts? Thank you.

Topic: 4421 Message: 4423

Hi Ken

I use RG-6 for all my feeds (because I can get the stuff for nothing as I work in the CATV industry here in the UK). I never have any problems. The cable itself is usually of a good spec (losses similar to RG-213).

Of course, the natural impedence of a dipole is 75-ohm so it lends itself well to that use. Most transceivers can handle impedences between 35 and 75 ohms (check out the specifications) and in any case, a tuner will null out any mis-match.

"suck it and see" is always my approach !

Good Luck

73, Rob

4424. Re: [ham-antennas] RG-6 Coax

Yahoo group: ham-antennas (2008)
Date: 2008-03-15 15:09:38 UTC
From: Phil Bader
Topic: 4421 Message: 4424

I used RG6 with all my MATV installations in the latter years of my service shop for UHF/VHF Tv antennas.
Before that it was RG59- very lossy. The newer RG6 is lower loss,has a good solid shield,and is low loss up into the UHF. Only problem is it has steel braid, and aluminum foil under that. Can't really solder to that. The more traditional coaxes used for ham is usually RG58u (mobile coax) and RG8U. Both lossy especially as you go up in the UHF frequency. As the other fellow points out, in the HF, if a tuner is used, so what? And with the RG6's good UHF characteristics, is't a shoe-in for 2 meters and up.
I just don't know how flexable it would be hanging from a dipole swinging to and fro for years.
Best,
Phil B

Anyone have any pro's and con's about this kind of cable. I know it is
75 ohm. Any information would be helpful.

use the self support rg6 , like what is used for drops, that will
keep the stress off of the connectors.

Phil is quite right about the soldering problems. I am ok 'cos I have "snap-and-seal" f connecting equipment so no soldering necessary.

So far as the flexibility goes, I agree, I would not want the solid cable to be flapping in the wind. I use RG6 for my dipoles but the cable is strapped to the pole 2 or 3 feet from the centre feed point.

Regards
Rob

I spent two days doing back to back tests between a G5RV and dipoles at the same height.

The half wave dipoles were consistently better on each band - usually 1-2 S points better, sometimes more.

I couldn't believe the results so repeated the tests again in a different location. Same results.

I can give you the full test result sheet if you want.

Isn't the point of the G5RV that it is one antenna for multi-band use? I would imagine that a dipole, cut and tuned to a dedicated frequency would be more efficient and perorm better. But, you would have to have many antennas to cover it all. I guess it's about compromise. These military type 15 foot vertical whips used on trucks for HF use with a tuner is really a trade off too,but it's a practical compromise. Were your test antennas up relatively high, or like a NVIS?
What you say makes sense,tho. Whenever possible, go for the tuned dipole.
Best,
Phil

With ladder line, the losses can be very, very low. But with coax, even part of the way, the G5RV would see some of the signal lost in the mismatch. So, I can see a dipole performing better.

Hi all,
Thanks for all the kind words. We live in Oklahoma.
We have moved my uncle back into his home and hired a live in nurse.
That will be better for him all the way around. We had tried to get him
closer to us but we might as well lock him up into a prison. I spent
the day wiring his house with web cams. So he will have all his rigs
just like always. Should have done this to start with.

Hi,

I have uploaded the G5RV v dipoles file as a PDF. It is called G5RV_v_dipoles.pdf in the files section

For the record it was fed with 35 feet of RG8. I would have expected the SWR on 14MHz to be lower, but it was the same when fed with 25 feet of RG58 in another location (4.5:1).

Hi Steve , Thanks for the information on the comparison of the your G5RV and the Dipole.
My Question, Was your G5RV build with matching section as described by Louis Varney,
You show that 20 meters had a very bad swr. I believe with the matching section that 20 meters should have had much better match.
http://www.qsl.net/aa3px/g5rv.htm
Thanks

From: steve95446
Topic: 565 Message: 4437

Hi, it was a commercially-produced G5RV with 102 ft length and 30ft 6 inches of windowed ladder line - I think it was the 300OOhm type with a spacing of just over half an inch.

I haven't measured it to see if the length was correct, but if I model it in MMana I get, low and behold, an SWR of 1:4.95 on 20m.

I guess the matching line is too short.

I'll look into it.

Steve G0KYA

4438. Re: G5RV

Yahoo group: ham-antennas (2008)
Date: 2008-03-16 15:16:38 UTC
From: steve95446
Topic: 565 Message: 4438

I think we are getting somewhere now. When tested, the top of the G5RV was hoisted on a 10m fibreglass pole. The end of the ladder line was basically at ground height. The ends were supported in an inverted V configuration at a height of about 2m (6ft).

I have now modelled this with MMANA and it is a lousy performer!

Radiation is basically upwards on 80-17m and SWR performance is also poor.

It seems that to get a G5RV to perform well it is much, much better as a flat top. And if you can get it higher even better.

As a lowish inverted V it doesn't work too well, which is probably what we saw in the results. I hope this helps.

Regards, Steve G0KYA

I have just added 2 x 4 foot copper rods as well as a decent amount of 7 core heavy duty earth wire which I stripped of insulator before laying into the ground about 6 feet from the shack here.

I'm only 5 years late (!) to get a proper station ground in because I was taught prior to taking my first exam that this is absolutely de rigour for any ham station. A necessity!

The thing is, I just don't understand why?

I too have a commercially made G5RV that I use exclusively. The configuration is up approximately 35 feet I use RG59u. The dipole is a winner for getting on HF 15, 20, 40 and 75 meters. It will perform on 160 meters as well but with modification.

For what it is you cannot beat if for time and money.

Subject: [SPAM][ham-antennas] Re: G5RV

Hi, it was a commercially-produced G5RV with 102 ft length and 30ft 6 inches of windowed ladder line - I think it was the 300Ohm type with a spacing of just over half an inch.

I haven't measured it to see if the length was correct, but if I model it in MMana I get, low and behold, an SWR of 1:4.95 on 20m.

I guess the matching line is too short.

I'll look into it.

Bill, and all:
I think you hit the nail on the head: "For what it is..."
True. I think we come to expect a certain antenna to be the "be all" antenna for everything. There is always compromise with any design. If one antenna was to be used overall, this is a good one. Don't throw it out because of a few flaws.
Best,
Phil

I don't know if "compromise" is the right word here.

If you want an antenna to be superlative at one thing, then you want
it to reject other things.

If you want the antenna to be a monster DX antenna, then you optimize
it for low-angle radiation - and MINIMIZE the high angle radiation,
because this improves your receive performance - you don't want to
hear noise from those directions.

This is not a compromise...it's the desired behavior.

Similarly, NVIS operation intentionlly excludes low-angle radiation,
because to the NVIS operator, DX is noise.

Neither is a compromise; both are optimized for their intended operations.

It's not a matter than you can't have a do-everything antenna - it's
that you don't want one!

Well, now as far as not wanting an "everything antenna", Sometimes it's not want but rather need. Many must choose due to space and other restrictions , one everything antenna of sorts. I simply meant sometimes one indeed does compromise for sake of space,heigth,etc in order to get on the air. And any antenna system has it's strengths and weaknesses.

Steve,
I think that you maybe finding the "flaw " in the Setup for the G5RV as you have indicate. Hope you find the reason for the high swr on 20 meters for it and will report back on the project.
Thanks 73 Ken

I can beleive that there is a difference.
I personally do not like the idea of an antenna that cannot work at some part of the band without a tuner. And the G5RV is known to need a tuner on any band, period.
I can run my dipole system on the top end of the 75 meter band without a tuner.
I used to have a 20/40 meter dipole, two dipoles with common center, and they could be used on part of the two bands without a tuner. And they most likely radiated reasonably well.
At one point, I put together a 75 meter dipole, left it long till I went to set it up. Took it on a camping trip, set it up and then tuned it for best SWR where I was going tooperate. Worked very well for me, and I did not have to mess with a tuner.
Simpler is far often actually better...
YMMV

4447. Link Antenna Tuner

Yahoo group: ham-antennas (2008)
Date: 2008-03-17 18:24:44 UTC
From: aa5wg
Topic: 4447 Message: 4447

Hi everyone:
I read a center fed multiband dipole, with open ladder line, should have its "transmission line" cut at even or odd 1/4 wave lengths for a given frequency. The starting point for measuring the 1/4 wavelengths sections starts at the antenna input and extends all the way to the link antenna coupler.

Another book said the even or odd 1/4 wavelength measurments starts at the end of the antenna and extends down the transmision line to the link antenna coupler.

Which of the above starting points for measuring even or odd 1/4 wavelength lengths is correct (antenna input or at the end of the antenna)?

Thank you.
Chuck - AA5WG

Bonner/Jim,
I have had direct burial RG8 buried for several years with any problem, it goes out to the back yard and feeds my antenna there about 75 ' away.
Now grant you there are some feed lines that will not tolerate being on or near the ground like twin lead, open line and the like.
Depends on what band and what your operation if the 4' will do, NVIS on 75 should work good, and I have worked AZ from MS when he was using 2 ft off the ground NVIS on 20 meters running 100 watts and less.
Hope you will give it a try and give us a report, I think you will be surprised!
73 Ken

Subject: [ham-antennas] Link Antenna Tuner

Hi everyone:
I read a center fed multiband dipole, with open ladder line, should
have its "transmission line" cut at even or odd 1/4 wave lengths
for a given frequency. The starting point for measuring the 1/4
wavelengths sections starts at the antenna input and extends all the
way to the link antenna coupler.

Another book said the even or odd 1/4 wavelength measurments starts at
the end of the antenna and extends down the transmision line to the
link antenna coupler.

Which of the above starting points for measuring even or odd 1/4
wavelength lengths is correct (antenna input or at the end of the
antenna)?

Thank you.
Chuck - AA5WG

From: Keith
Topic: 4453 Message: 4453

I realize this group is for ham antennas but are questions about 11 meter antennas permitted here?
I have questions about quad antennas I haven't found suitable answers to on the internet or in any antenna books I've read.

I've received conflicting answers about questions I've asked a few extra class hams that should be in the know.
The conflicting answers I get have merit in some ways but they can't both be true.

Thanks

KM

Hello Keith,

I have built a few 11 meter antennas in my time. The best one was a mono-band 3 element yagi for 11m. It was marvellous and I had it up at around 80 feet or so. Quads can be great but a mono-band quad is hardly worthwhile for you. Hams generally build them because they are easy(ish) to make into multi-band antennas to suit 20, 15 and 10m (for instance).

I did once have a manufactured quad made by (I think Avanti). It was a PDL-2 ☐ damned fantastic beast it was - and switchable from vertical to horizontal too. Bulky though. The three element was lots easier and simple to maintain, more so than the quad!

Anyway ☐ shoot away old boy, have no fear here. Antennas are fun regardless of frequency :)

4460. Re: Quad Questions

Yahoo group: ham-antennas (2008)
Date: 2008-03-20 06:03:34 UTC
From: Keith
Topic: 4453 Message: 4460

My first question is about a matching system for the quad.
I've ruled out the available manufactured Baluns due to their physical size.
Regardless of the way they are orientated on the spreader arm they will put the driven loop out of alignment.
Two points of the driven loop will be misaligned with the rest of the loops making the driven loop larger than the reflector on one side.
I don't want it being confused as to which direction it should be directional.

That leaves two types of matching systems that I'm aware of, a 1/4 WL of 75 ohm coax for a matching system or a coax Balun like "The Ugly Balun".
Both can be done in a way that doesn't misassign the driven loop from the other loops.

Which is better, a 1/4 WL of 75 ohm coax or a coax Balun?
What about a 1/4 WL of 75 ohm coax made into a coax Balun?
Would there be any advantage in using the 1/4 WL of 75 ohm coax in a coax Balun?

I'm leaning towards the coax "Ugly" Balun for the simple reason it offers the option of dual polarity with a single coax feedline if done correctly and I have yet to figure out that option with a 1/4 WL of 75 ohm coax.
I have an MFJ 259B and use it to do my coax and tune my omni ground plane which is spot on and works well for the location it's in being I'm located down in a hole in a flood zone and my nearest neighbors are at 100-200 feet higher elevation.
To be on the same playing field with them I would have to have a 150-200 foot tower to be near the same elevation antenna wise.
On a small lot with limited room to work with I want to maximize a directional antenna the best I can whatever it may be.

The max boom length I can do here is about 22 feet with the best location on a 7,500 square foot lot.
Not a lot of room to work with having trees, storage buildings and such to work around.
That leads me to my next question.
I would love to build a six element quad but just don't have enough room for it, the best I can do is a 5 element on a 22 foot boom and that's a squeeze with a little tree trimming.

My next question is about conductive material inside the loops of the quad.
A 5 element will place the first director within a foot of the

support mast.
What effect will a conductive mast have being that close to the first director loop?
Would a nonconductive mast be better in that situation?
With a nonconductive mast and the coax feedline ran outside the loops so not to interfere is my thoughts on the deal.

I've read about wire size ratio having an effect and comes into play in a quad design but my thoughts are on that at 11 meters the ratio is so small it doesn't matter much, it's a very small ratio compared to the loop size.
It may be enough of a factor in higher frequencies when the ratio is higher but not that big of a deal at 11 meters.
That's what I've been told by some that are in the know but have been told different by others about the conductive mast part of the design.
It is a small ratio of the loop size at 11 meters but the conductive mast is also 50% of the pattern when vertical mode.

Will a conductive mast less than a foot from the first director have an adverse effect on the antenna or not?
I think it will and I should use a non conductive mast with the coax outside the loop so there is nothing conductive inside the loops.

Enough for now, it's late here.

Thanks

Keith

This makes sense. The matching/feed system in the G5RV is lossy. I recommend multiple dipoles on the same feed line over the G5RV.

I spent two days doing back to back tests between a G5RV and dipoles at the same height.

The half wave dipoles were consistently better on each band - usually 1-2 S points better, sometimes more.

I couldn't believe the results so repeated the tests again in a different location. Same results.

I can give you the full test result sheet if you want.

If you're only running 5W (any more than that on 11M is illegal), then neither the balun or conductive mast issue is anything to be concerned about.

I also agree with another poster that suggested a yagi was a better design for a monoband gain antenna in your situation.

Brian AC7NA

P.S. Borrow a copy of the ARRL Antenna Book from one of your Extra friends. It will explain in detail anything you need to know in order to understand anteena theory and operation, including quads.

4463. RE: [ham-antennas] Re: Quad Questions

Yahoo group: ham-antennas (2008)
Date: 2008-03-20 16:13:05 UTC
From: Callum M0MCX
Topic: 4453 Message: 4463

Keith,

Frankly, I would say the 1/4 wave stub sounds the best matching idea since it's cheap and easy. Work out the natural impedance then match it afterwards.

For the wavelength you are on, with the horizontal polarisation, I would not worry in the slightest about the tower getting in the way of you antenna. Plenty of people do this with 6, 2 and 70cms quads on aluminium poles and they never complain. Lower down the frequency spectrum, this will be a breeze.

In terms of flood plain and competing with stations 200 feet above you, for DX this is irrelevant - unless you are trying to communicate line of sight (ground wave). DX will only require a 5 to 10 degree elevation from you to horizon.

May I ask what antenna you are running with now...?

Callum McCormick

What about a 1/4 WL of 75 ohm coax made into a coax Balun?
Would there be any advantage in using the 1/4 WL of 75 ohm coax in a coax Balun?

I'm leaning towards the coax "Ugly" Balun for the simple reason it offers the option of dual polarity with a single coax feedline if done correctly and I have yet to figure out that option with a 1/4 WL of 75 ohm coax.
I have an MFJ 259B and use it to do my coax and tune my omni ground plane which is spot on and works well for the location it's in being I'm located down in a hole in a flood zone and my nearest neighbors are at 100-200 feet higher elevation.
To be on the same playing field with them I would have to have a 150-200 foot tower to be near the same elevation antenna wise.
On a small lot with limited room to work with I want to maximize a directional antenna the best I can whatever it may be.

The max boom length I can do here is about 22 feet with the best location on a 7,500 square foot lot.
Not a lot of room to work with having trees, storage buildings and such to work around.
That leads me to my next question.
I would love to build a six element quad but just don't have enough room for it, the best I can do is a 5 element on a 22 foot boom and that's a squeeze with a little tree trimming.

My next question is about conductive material inside the loops of the quad.
A 5 element will place the first director within a foot of the support mast.
What effect will a conductive mast have being that close to the first director loop?
Would a nonconductive mast be better in that situation?
With a nonconductive mast and the coax feedline ran outside the loops so not to interfere is my thoughts on the deal.

I've read about wire size ratio having an effect and comes into play in a quad design but my thoughts are on that at 11 meters the ratio is so small it doesn't matter much, it's a very small ratio compared to the loop size.
It may be enough of a factor in higher frequencies when the ratio is higher but not that big of a deal at 11 meters.
That's what I've been told by some that are in the know but have been told different by others about the conductive mast part of the design.
It is a small ratio of the loop size at 11 meters but the conductive mast is also 50% of the pattern when vertical mode.

Will a conductive mast less than a foot from the first director have an adverse effect on the antenna or not?

I think it will and I should use a non conductive mast with the coax
outside the loop so there is nothing conductive inside the loops.

Enough for now, it's late here.

Thanks

Keith

Callum

For my omni I'm currently running a .640 23' DC ground version of the
Avanti Sigma with dual tuning slides I built.
It works well, no more static charge build up and a lot less noise.
I can hear better than those at higher elevations with taller
antennas.

The quad will be used mostly on vertical, that's why my concern with
the mast being close to the first director.
If it were horizontal only it wouldn't matter.
I plan to make it dual polarity switchable with a single coax
feedline after I get the matching system worked out and working well.
I would love to build a 6 element quad but only have enough room for
a 5 element with a 22' boom.

I ran a PDL 2 for a while but wasn't crazy about it.
My omni could hear better than the PDL 2. The only advantage the PDL
2 had was good back rejection but it had a wide pattern on the front
end.

As a kid, before I got my ticket, I did alot of experimenting with antennas for 11M.

Here are some of the results.

I experimented with the Quad design. It was a big monster even on 11.

Using a quad reflector behind a home-made veritcal dipole (like the shakespear big stick) gave a 1/2 dB signal gain to a station I was pointed to who was a few miles away.

It worked, not as well as I expected.

Now, as far as matching goes, being that I have built quads and quagis for 2 meters and 440mhs, a full wave loop (as I remember reading) is very close to 50 ohms at resonance. I have never used any kind on matching device on my 2 meter quad, or the 44o quad. I was able to trim them to low SWR at the band centers, with a direct connect to RG213. Using 1/4" soft copper pipe for the elements gave me a very good band width - more than 10 mhz on 2 meters before the SWR approaches 2:1

Bear in mind that a 11meter quad is a big beast. You may want to consider making a yagi. Also, a vertically polarized antenna will always be "noisier" than a horizontal antenna - man-made noise is vertically polarized in nature. But since most CB ops use vertical antennas, best to stay that way.

Good luck with the project - sounds interesting.

From: Callum M0MCX
Topic: 4453 Message: 4466

Some good pointers from Ian..

Keith - I now realise why vertical polarisation is important. I did place my 3 element beam in a vertical configuration once and the gain was great. The driven element was only about 18 inches from a scaffolding pole that held it up and the feedpoint was same distance from the rotator too. Seemed to make no difference. Just go build it my friend and don't worry about the tower causing pattern deformation. There's nothing you can do about it anyway.

Have you thought about a yagi instead of a quad..? You could build it lots easier, more elements and probably just as good an antenna..?

I'll be happy to model one for you on a boom length of 22 feet, say a 4 element..? At least with a 4 element version, the driven element and reflector are further away from the tower.

?

Cheers,

Callum McCormick

4467. Alpha Delta Coax Switches FS

Yahoo group: ham-antennas (2008)
Date: 2008-03-21 16:42:23 UTC
From: Ken Simpson, W8EK
Topic: 4467 Message: 4467

For Sale:

Coax switches by Alpha Delta

Delta 4
This is a coax switch designed to switch four antennas.
It actually has a fifth position that will ground all antennas.
There is also a special lightning arrester "plug" built in
that can be changed if you get hit. The switch is of strip
line type construction so that it provides a good impedance
match at higher frequencies; it is rated for use through 450
MHz. Of course it will handle a full 1500 Watts. SO-239
connectors. This is a very high quality coax switch!
This particular switch works just like it should, and looks
very close to new. With paper work for $65 .

Delta 2
Same as Delta 4 above, except it will only switch two
antennas, and has a third position to ground all antennas.
This one also works great and looks great also.
With paper work for $40

Prices do not include shipping from Florida.

Thanks.

73,

Ken, W8EK

I made a dipole on 20m and fed it directly with RG58U and SWR is I:1.5 on 14.150 BUT BUT the length of the dipole each side, after trimming, comes to 14feet instead of 16.9, what could be wrong??? why SWR is low even when the length of each side of dipole is not as per formula, that is 16.9 feet ??????

14feet instead of 16.9, what could be wrong???

Lots of reasons. From how high it is off the ground (ground loss), type of wire (gauge, covered or bare), how close it is to metal (gutters, tower, shed) and pronbably others. All that being said if all connections are correct don't worry about length. Remember a lot of antenna math is in a perfect world. Just like one antenna works for one ham but not another. As long as the swr is low to make the radio happy have fun...

From: Wayne Leake
Topic: 4453 Message: 4471

Regardless of what many are doing out there, a few things for 11 meter operation have not changed. It is illegal to have an antenna mounter higher than 20 feet above a tree, house, or building, including an existing tower for other services. Otherwise it is 60 feet for an antenna and tower/mast put up just for CB use.
External amplifiers are not legal in any sahpe or form. this does not include receiver preamps.
Someone in one of the answers mentioned DX. In all of the USA and areas controlled by same, it is illegal on 11 meter class D CB to talk, or attempt to talk more than 250 Kilometers, about 153 miles.

I am not an expert on Quads, preferring Yagi designs, but I have seen a few drawbacks along the line with them.
Support arms breaking, usually not made strong enough. PVC is a poor choice for anything below the two meter band, in my opinion, and even there one needs to consider it is weak and will deteriorate in the sun and heat. Even Fiberglas, if not well designed and protected, will deteriorate.. I once got a handful of fiberglas splinters from a fiberglas anenna that I was going to salvage to use on ten meters.
The polarization can be off kilter if the desing or antenna is not fed correctly. Trying for dual polarity from one feed line didvides the siganl between the two, so will not work as well as using two feedlines, or a switching system at the antenna feed.
I once looked at a quad made for 11 meters being sold as dual polarity. Turns out it was neither, but halfway in between. While it worked, it was a severe compromise. For most legal 11 meter use, it is better to simply stick with vertical polarity, as very few mobiles will be using horizontal...
Using a non metallic mast to mount a large 11 meter quad is begging for trouble down the road. Simply not sturdy enough to support such an item. Even using too weak a metal mast can be a problem eventually.
Designe right, the metal mast will have little effect on the antennas elements, as long as not mounted so element is too close. And, as was pointed out, with horizontal polarity, the vertical mast will heve negligible effect.
YMMV

Very true. I've been surprised more than once with my calculations. It is very common to have to make adjustments, and sometimes way off from what you expected. I find this to be true with verticals, dipoles, J-Poles and so forth. Verticals can vary tremendously with the surrounding objects, grounding and radials, etc.

There are times when it is a bad sign. For instance, I had a dipole for 10m that had a perfect match across the entire band, on the first try. Well, I also had a ton of coaxial loss. Good matches with verticals (50 ohms) is bad a thing. A good vertical should be in the range of more like 35 ohms.

Experimenting with antennas is a ton of fun.

I'll be off-line for a few days so I'll reply now. In my country, nobody gives a stuff what you do with RF in the community, as long as you don't cause local interference (and you are respectful .. which is mandatory in my book anyway).

Some people seem to get extremely irate because a particular rule says one darned thing and someone else goes and does another. I originally started off as an 11 meter operator and almost exclusively talked to the USA with my 11m yagi. The local authorities actually worked WITH me to get over the RF issues I was having next door - and allowed me to continue operating illegally then! 25 years later, some folks seem to think that I must have been a retard to be involved with this stuff. Actually, maybe I was - but I don't care because nobody got hurt and it did no harm to anyone anywhere. I only passed on pleasure by exchanging happy messages around the world, much as I do now.

Today, I'm the founder/owner of a 10 million dollar enterprise (actually, it's more like seven million dollars [converting from pounds] - but it doesn't sound quite right..!) which is proof that exposing yourself to lots of RF when you are young makes a difference when you're older :) - Enjoy your radios folks, you only live once!!

Wyane, I am not being desrepecting you Sir - you sound like an honest, down to earth guy and your advice is sound; it's the anonomous folks that cause intentional QRM, complain without names and QSK with sad comments about everyone else that need to be named and shamed...

Go on Keith - build it man and I'll talk to you over here in the UK on any frequency you like. Although 10m would be a whole lot easier!! :)

I have to admit that I also enjoyed 11 meters as well back in the early 70's. And at one time, I had a Moonraker 6 antenna and a Johnson radio that did a real good job. Thats how I started learning how radios worked, and how to repair simple circuits. And with only 5 watts, I had to make up the difference with the antenna. That helped me learn about element length, spacing, feedline, boom lengths, and SWR. All of which have helped me to today. So, if it hadn't been for "CB" radios, and wanting more out of it as far as where I could talk, and not restricted to certain "channels", I may have never moved up to Ham Radio.

As far as the quad, I would agree, feed each separately. A-B switch....one for H, one for V.

Subject: [ham-antennas] Re: Quad Questions

Regardless of what many are doing out there, a few things for 11 meter operation have not changed. It is illegal to have an antenna mounter higher than 20 feet above a tree, house, or building, including an existing tower for other services. Otherwise it is 60 feet for an antenna and tower/mast put up just for CB use.
External amplifiers are not legal in any sahpe or form. this does not include receiver preamps.
Someone in one of the answers mentioned DX. In all of the USA and areas controlled by same, it is illegal on 11 meter class D CB to talk, or attempt to talk more than 250 Kilometers, about 153 miles.

I am not an expert on Quads, preferring Yagi designs, but I have seen a few drawbacks along the line with them.
Support arms breaking, usually not made strong enough. PVC is a poor choice for anything below the two meter band, in my opinion, and even there one needs to consider it is weak and will deteriorate in the sun and heat. Even Fiberglas, if not well designed and protected, will deteriorate.. I once got a handful of fiberglas splinters from a fiberglas anenna that I was going to salvage to use on ten meters.
The polarization can be off kilter if the desing or antenna is not fed correctly. Trying for dual polarity from one feed line didvides the siganl between the two, so will not work as well as using two feedlines, or a switching system at the antenna feed.
I once looked at a quad made for 11 meters being sold as dual polarity. Turns out it was neither, but halfway in between. While it worked, it was a severe compromise. For most legal 11 meter use, it is better to simply stick with vertical polarity, as very few mobiles will be using horizontal...
Using a non metallic mast to mount a large 11 meter quad is begging for trouble down the road. Simply not sturdy enough to support such an item. Even using too weak a metal mast can be a problem eventually.
Designe right, the metal mast will have little effect on the antennas elements, as long as not mounted so element is too close. And, as was pointed out, with horizontal polarity, the vertical mast will heve negligible effect.
YMMV

4475. Crushcraft 440 stacked dipole - Info/identify please?

Yahoo group: ham-antennas (2008)
Date: 2008-03-22 14:02:30 UTC
From: John P.
Topic: 4417 Message: 4475

I was given a Crushcraft (stamped name) 440 stacked vertical dipole. It is 4 elements that have been mounted on an 8 foot boom (vertical). It has the coaxial feeds all set up.
I am trying to identify this item and have been unable to locate any data at all.

Can anyone offer any info please?

Thanks

Well, first, it's Cushcraft, not cRushcraft, so maybe hard to search. Went to their site,searched 440, and vertical. Try here.

Is it an 8 foot mast with 4 loops spaced from top to bottom with the feedlines molded into each other with one connector at the end? If so, it is probably a Commercial antenna cut for a commercial band. They show up at hamfests from time to time and not usable on the Ham Bands. You can usually rotate the loops around the mast and vary the pattern of the antenna to favor (or eliminate) one direction. The best way to find out if it is useable is to get an Antenna Analyzer and sweep it to find its' tuned frequency. They are tuned very sharp and as I said probably can not be used on the ham band.

And yes, it is also probably a Cushcraft which make Ham antennas but also builds commercial stuff also.

The masts are usually pretty stout and can be used to hold up another antenna !!

Woops!

Misspelled it there but the link provided does not appear to be the antenna. As set up it consists of 4 dipoles, oriented vertically on an 8 foot vertical boom. The boots on the coax connectors say Cushcraft but I can not find any model/ID number on it.

Thanks!

No loops on this one. Just 4 dipoles vertically oriented on a vertical mast. It does have the feedlines molded into each other with one connector at the end/center.

Thanks!

That was closer but not quite.

I can also tell you that each of the dipoles has a gama match. Maybe that helps.

Thanks for your efforts!!

I think I found it!

Here are 2 related links. The picture in the PDF looks exactly like the 4 dipole array that I have here!

http://www.eham.net/forums/TowerTalk/1322

http://www.cushcraft.com/support/pdf/951282.pdf

It seems that it is a Ham antenna and not a commercial one

Comments welcome!!

OK, now these are on the same principle as the loops going up the sides as I sent you.My example was simply folded dipoles. Common antenna type used in the business band 470MHz service. They had a directional design. Position those dipoles around the pole. When we submitted our request for a 470 business band channel the FCC researched our areas taking into account other nearby station licencees, terain,etc. Some antennas had to have directional abilities to avoid interference to other services,etc., as wea the actual freq. given. Good hunting!

I think I found it!

Here are 2 related links. The picture in the PDF looks exactly like the 4 dipole array that I have here!

http://www.eham.net/forums/TowerTalk/1322

http://www.cushcraft.com/support/pdf/951282.pdf

It seems that it is a Ham antenna and not a commercial one

Comments welcome!!

Woops!

Misspelled it there but the link provided does not appear to be the antenna. As set up it consists of 4 dipoles, oriented vertically on an 8 foot vertical boom. The boots on the coax connectors say Cushcraft but I can not find any model/ID number on it.

Thanks!

Subject: [ham-antennas] Crushcraft 440 stacked dipole - Info/identify please?

I was given a Crushcraft (stamped name) 440 stacked vertical dipole. It is 4 elements that have been mounted on an 8 foot boom (vertical). It has the coaxial feeds all set up.
I am trying to identify this item and have been unable to locate any data at all.

Can anyone offer any info please?

Thanks

Now that I have the info on it I will either try to put it on eBay (probably without the mast), or take the complete assembly to the local swap meet in a couple of months. I will research further though, to see what a fair price range would be.

Who knows what may come of it!

73's

Phil Bader <PBADER@...> wrote:
OK, now these are on the same principle as the loops going up the sides as I sent you.My example was simply folded dipoles. Common antenna type used in the business band 470MHz service. They had a directional design. Position those dipoles around the pole. When we submitted our request for a 470 business band channel the FCC researched our areas taking into account other nearby station licencees, terain,etc. Some antennas had to have directional abilities to avoid interference to other services,etc., as wea the actual freq. given. Good hunting!

4488. effective Ground Radial System

Yahoo group: ham-antennas (2008)
Date: 2008-03-26 16:19:13 UTC
From: Steve Hunt
Topic: 4488 Message: 4488

Hi all,

I am new to the group, new to HF and new to building Antenna's.

Wow... alot of NEW's just call me Newbee

I need to build a Radial System for my newly aquired Zero Five 43' Vertical.

My Back Yard is 75' wide and 85' long and I will try to cover as much ground as I can. I have read so many Articles on effective Radial's that my Head is spinning.

I want to lay the Radials (I will try to cut 120 Radials) on top of the grass and use 5" SOD-Staples or just buy some 10 AWG solid copper and make my own staples... So I can staple the Radials down and let the grass grow over the Radials.

My big Q is: Is it important to use Nr 14 AWG solid copper wire? or can I use 16 or even 18 gauge? possibly even stranded?

I am having a hard time finding 14 AWG solid copper cheap!!

I really can't spend 300$ just for the Radial System.

Can someone offer a website and order nr for the wire I would need?

And last.. maybe some advise?

I do have some obsticles in the Yard... and I know... they really do not matter as long as I cover as much ground as possible. The Antenna is 43' Tall and I will cut the Radials at mostly 45'... about 30 Radials will only be 20' but to one side I can cut about 20 Radials to 100' (into the neighbors yard). I live in NH and I guess what I have been told the ground-conductivity is "Average".

73 to all

Hello Steve - I think you have pretty much already engineered about everything - Sounds like a pretty decent system and as you say, you are already covering about every sq. inch that is available to you. With the price of copper being what it is, You would possibly be ahead by buying your copper locally as to avoid shipping cost. I know there will be a few with the impression that 14 would be better than 16 or 18 but with the amount of radials you are planning I doubt you could ever tell the difference other than with a fancy piece of software. I seriously doubt the difference would ever be seen or heard on your signal. I think you have it worked out pretty well for a Newbie or an Oldie either one. Will be good to hear your big signal and see how it goes for you ---- 73 de N?ATH / Dave

4490. Re: [ham-antennas] effective Ground Radial System

Yahoo group: ham-antennas (2008)
Date: 2008-03-26 17:31:42 UTC
From: Arthur Nienhouse
Topic: 4488 Message: 4490

Hi Steve
I cut up 1000 ft of #14 house wire into 66ft lengths then wound
them to the spool hooking the ends to gather then installed them
out and around on a home brew spool caddy using 3/32 welding
rod or clothes hangers cut up and bent over length about 6" for
staples if radial length is a problem bend them around.

But what really did the trick was the Aluminum Gutter Guard
stapled to the ground same as the wire. The ends were captured
to 6 ground stakes that had the top end drilled and tapped 1/4 x 20
each 2 ft from each tower leg in a circle around the Hy Tower legs
I used stainless hardware threaded rod, nuts and bolts and 3" fender
washers with 1/4" center hole the sandwich was buttered with
Noalox from the electrical supply house 8 years ago. It still is
performing well the gutter guard caused the feed impedance to
go low requiring a step up coil across the feed to get to 50 ohms.

You can see the Hy Tower rebuild and the motorized air core
inductor that puts the antenna on 160 with very good performance,
at ka9zap.com
The 40 meter stub had to be made of much stiffer tubing 1" to stop
it from flexing in the wind which would change the swr tuning on 160.
The grass grew and all the wire and gutter guard can not be seen.
The yard is very small 50 ft on a side with the antenna off center.

Regards
Art

The size of the wire does not matter as it not carrying 'current' in
the traditional sense.

You may try salvage yards, as the have piles of with that the
will 'back-sell' you at slightly more than scrap prices.

As you dont care about looks or kinks, ect. your gonna bury it
remember.

100 radials is about the ARRL feasible limit, I think.

I bought a half mile of aluminum electric fence wire from my local agricultural supply store for $35 last year.

But...if you can get the base of the vertical off the ground by 12-15 feet, you then only need 2-4 tuned radials per band. I put four tuned radials under mine, for each of 80/40/20 meters; that seems to do it for all bands. If I can hear DX with this antenna, I can work it. This was not true when it was ground-mounted with lots of radials.

Go to the ARRL website and google "W2FMI" and read his articles on elevated radial fields from the 1980s.

A simple and very effective vertical can be "planted" using one 12 foot 4X4 post to hold the vertical in the air, and two more to hold the ends of tuned radials. If the radials are high enough, not only is the whole system de-coupled from the lossy earth, but family, lawnmowers and tractors can safely traverl under them.

2640 feet of aluminum wire? What gauge was it?
Most of the aluminum wire I have dealt with was 12 or 14 solid, and was
far more costly than that. We used to buy it in boxes that were 50 foot
coils, for antenna ground leads when we installed TV antennas. But those
were maybe 500 feet per box. Don't recall exactly now.
And aluminum has gone up a lot since back then.
YMMV

They will detune an antenna which means that they should work as an antenna but you would need a really wild match box to use one, it seems to my mind, but then I have loaded up string dipped in saltwater and it worked until it dried out. I think it is more amazing what wont work.

The antenna ground lead aluminum was typically 8 or 10 gauge.

Electric fence wire is available as 17 or 14 gauge. I used 17 gauge.
Aluminum can support itself without sag for a longer distance than
copper because of its lower weight...that's why the power drop to your
house is aluminum, not copper.

2640 feet of aluminum wire? What gauge was it?
Most of the aluminum wire I have dealt with was 12 or 14 solid, and was
far more costly than that. We used to buy it in boxes that were 50 foot
coils, for antenna ground leads when we installed TV antennas. But those
were maybe 500 feet per box. Don't recall exactly now.
And aluminum has gone up a lot since back then.
YMMV

It is easier to build a J Pole, which will give good results.
I have been using a dual band J Pole for several years now, in 3 different locations.
Aluminum rod and tubing along with a heavy aluminum angle are the basic pars I used, along with a U Bolt clamp, and 3/8" by 24 nuts and washers, plus an adapter from Radio Shack for the feed.
I also built one for the 222 to 2225 MHz band first.

Many make theirs from Copper pipe and fittings, but I have seen too many problems with those, including using coax cable with an open end that will allow water to get in. the type I use allows me to use any good cable with PL259 connectors, and tape it over to help keep water and moisture out.

As far as I know, it has better gain compared to a ground plane, is broader banded and very durable when well constructed.
YMMV

You made me go look at the receipt. I was in error in a couple ways. First off, yes it's aluminum...I knew I'd got that part right. But...the spool is 1/4 mile, not 1/2, and it's 14 gauge, not 17. Price paid was $36.50 last year from Pacific Harvest, an ag supply store here in Oregon. I'm sure it's gone up since then, as all metals have risen.

> it should be directional.

You might consider mounting the quad so that the spreaders are horizontal and vertical rather than at 45 degrees. That way, you could strap a 1:1 balun right to the spreader. You don't need a huge one for 12w pep on 11M and you can often just connect the coax direct. For horizontal polarization. feed it at the bottom, though for most 11M work, you really want vertical polarization and should feed it at the side. Even if there is some distortion due to spreader bending, as long as the area of the driven element stays about the same, the design will work. Make the driven element's perimeter about an inch shy of 37 feet and the reflector about 38 feet 9.5 inches. The only real drawback to this diamond orientation is that the turning radius is a bit bigger.

You can, to some extent, tune the impedance in a 3+ element design by adjusting the spacing of the element immediately in front of the driven element. A good way to tune is to upend it on the ground pointing it straight up and make your adjustments there with a begged, bought or borrowed analyzer. Even an SWR bridge near the feedpoint can tell you a lot. It's quite feasible to make a quad that has 50 ohm resistive impedance at the feedpoint, thus making matching networks unnecessary. Might be a tad harder to do it with switchable polarity, though.

Vertical is probably best for most local work. Horizontal will have an edge over it for long terrestrial paths or skip. I did have a good location back when I played with 11M and I could work 100 miles quite easily with 12w PEP and just a half-wave vertical antenna.

Any length that produces a complex impedance that your tuner can
efficiently match is OK. If the antenna is reasonably effective,
this usually means that only a few lengths are actually awkward.

Well, I just did a Google search for "aluminum clothesline wire" and
found a number of mail-order sources for it. It appears that 9-gauge
"blue coated" aluminum clothesline wire is offered by the Hillman
Company. This is a major supplier of fasteners and other home
handyman hardware to stores like Home Depot. Perhaps a Big Box
hardware store is a place to check for it. Typical online prices
appear to be $7 for a 50 foot spool, and when you order multiple
spools, they're all connected together, up to 12 spools.

I made my first two meter beam out of large-gauge aluminum clothesline
wire...but it was not 'coated'.

Topic: 4499 Message: 4509

I don't have actual pictures of mine available right now, as they are on another computer.
Go to : <http://www.arrowantennas.com/> and look at their J Poles.
Mine look slightly different being as I used both rod and tubing for parts of mine.
The one I made for the 222-225 MHz band is actually adjustable, as I used a small section of tubing on the tops of the elements. Plus I had to splice two rods togeher for my dual band on the longest element.
Eventually I will get all of my pictures consolidated and put them on my web site.
This type of J Pole when built right is very solid, and will withstand rather high winds.
One of the difficult parts is threading one end of the rods for 3/8" by 24 thread. I managed to get mine slightly off on a couple of the elements.
Mostly basic tools required, and a 3/8 by 24 die and holder for the threading.
Beware the cheap tap and die sets. Some are made to very poor specs. I wish I still had the set that vanished back in the mid 70's.
I threaded the holes in the angle, except for the one for the driven element, and by using nuts and washers on both sides of the angle, was able to tighten adequately that they will not come apart. I also used a tad on NoAlox where the pieces join to other parts. Especially on the threads. I used mainly stainless steel nuts. Aluminum nuts and washers would be okay, but harder to locate.
The aluminum angle needs to be heavy, not the thin cheaper stuff. I used one chunk cut into two for my J Poles. They can be built for virtually any band, but as you go down in frequency, the elements become larger. A version for six meter would have the taller element at almost 14 feet, and the shorter element about 4.6 feet. Not exact, as I rounded things off a bit there.
For two meters and up you are looking at under 5 feet tall for the antenna.
YMMV

what I was looking for was more on the order of the aluminum close
line wire that you could buy years ago, I think that stuff was on the
order of #6 or #8 ga. I remember some projects years ago where they
used that for the elements in two meter and 440 beams. Also in small
VHF and UHF quads. But I haven been able to find any yet.
> Danny
> WB9RIM

Well, I just did a Google search for "aluminum clothesline wire" and
found a number of mail-order sources for it. It appears that 9-gauge
"blue coated" aluminum clothesline wire is offered by the Hillman
Company. This is a major supplier of fasteners and other home
handyman hardware to stores like Home Depot. Perhaps a Big Box
hardware store is a place to check for it. Typical online prices
appear to be $7 for a 50 foot spool, and when you order multiple
spools, they're all connected together, up to 12 spools.

I made my first two meter beam out of large-gauge aluminum clothesline
wire...but it was not 'coated'.

Seems to be getting harder to find many things.
Places to look:
Ace Hardware.
OSH (Orchard Supply Hardware) in California.
Home Despot, maybe, their inventory varies with region and how well they reorder.
Lowes Home improvement. Another maybe, but often better than H D...
May be other places, and this can vary depending on where you live.

OSH carries (Or did) a fair amount of aluminum material, tubing (heavy stuff) rod, angle and so on.
That is where I got most of the material I used for several antennas.
Ace might or might not have some of it.

Oh, and when I wanted guy wire, I had to search a bit. I forget what they sell it as now (stranded galvanized stuff).
YMMV

For what it's worth, I have one of Arrows factory made J-poles and it works great. Unless you have the stuff or just want to do it yourself, I don't think you are going to save much over just buying one.

From: John P.
Topic: 4468 Message: 4513

There are some other variables that need to be considered.....

1. Are you measuring the SWR close to the antenna or many (50+ for example) feet away?

2. How close to the ground is it?

3. What is close to it - trees, fences, aluminum sided house/building?

4. What is being used to support it - center, ends, etc?

5. Try reorientigng the antenna and see if anything changes.

Revisiting #1 above, there is a chart on the web (you'll have to search for it) that plots the SWR measured at the transmitter relative to the line losses including coax cable type & length.

Good Luck!

Your dipole is close to the ground or is capacity-coupled to
whatever is supporting it?

4514. Optimize G5RV?

Yahoo group: ham-antennas (2008)
Date: 2008-03-29 02:10:02 UTC
From: frostbitnome
Topic: 4514 Message: 4514

Hi Guys,

New here, name is Nate, KL3NP. I am in Nome, Alaska. Brand new to HF, I have just put up one of Kerry WA2NAN's 102' G5RV's, but it sure does not have the ears I hoped.

I mounted the center up on a 21' aluminum pole anchored to the eave of my house, the top of the pole perhaps 8 feet above the roof. The ends I strung out in an inverted "v", they about 3' above the ground at their anchorings. I have the feed line (its 100 feet long, 30' of ladder line mated to 70 feet of coax) running almost perpendicular to the antenna legs, the 30' ladder line has a small droop and is anchored to the side of my garage at its end (wood siding). I then ran the coax into the house, though 50' or more of it is coiled up in the closet. I was told I need the full 100' for it to work properly.

My radio is a Yaesu FT-857D and the tuner is an LDG AT100pro.

I know its location, or height, is not optimum, so I would like to hear what you folks would recommend I do if it were yours.

Thanks much, I appreciate your comments.

IMHO.

I would dump the coax and use 450 ohm ladder line. Use the coax to build a air choke and run the coax into your tuner as they seem to like the coax connections better. The lower capacity ones anyway.

Also from what I have read from others on this list you might want to try flat topping it rather than invert V or sloper. BTW I have lived in Anchorage twice. Did you get to see the finish of this years race?

Hi,

The tests I have done show that the G5RV doesn't like being an inverted V, especially if the ends are that close to the ground.

As a test, see if raising the ends, perhaps on fibreglass fishing poles, helps at all.

All the tests I have done with inverted V G5RVs show that it is down 1-3 S points on a resonant half-wave dipole.

Flat top at 35feet and it gets close to a dipole.

If you woud like e-mail me and I will let you have the MMANA modelling that I have done.

Steve G0KYA

The aluminum J Poles could be made so they can be easily portable. The dual bander by using a long 3/8 by 24 nut in the middle of the longest element, and the 222-225 MHz version is short enough as it is. I have some pictures of the 222-225 MHz version I built in the photos on the ham help group.
<http://ph.groups.yahoo.com/group/HamRadioHelpGroup/photos/view/588a?b=1>
The Arrow Antenna versions can be bought for $39.99 eah plus shipping for those who don't want to roll theirown.
I personally loike building antennas when I can.
YMMV

My buddy made one, 5 elements in total. The whole thing was made of copper pipe with a 2x4 as a boom.

It was a crazy looking contraption, but it did indeed work pretty well.

No idea of what the rated gain was, but it definitely had nice front-to-back properties and he was able to work me on simplex with 5w and very solid signal when normally 20W on a j-pole was required for a similar result. It definitely had some gain.

http://members.aol.com/n2kbk/quagi.html

http://kk5bl.tripod.com/quagi.html

The Quagi is a nice diy gain antenna. The second site
if for a ten element 2 meter quagi . . The author says
a 14 db gain. 17.8 ft . . imagine if you only used 5
elements and got it under nine feet . . or 4 and got
it under 8 feet.

Just another decent antenna for gain at 2 meters and
higher.

For a dual-band, easy to assemble, easy to transport antenna take a look at the DBJ-1 [1] and DBJ-2 [2].

[1] http://www.arrl.org/tis/info/pdf/0302038.pdf
[2] http://www.arrl.org/qst/2007/03/fong.pdf

The DBJ-1 is designed to be put inside a piece of PVC pipe for base station use and the DBJ-2 is designed to be hung up in a tree or other support.

I've made a few single band j-poles from twinlead and have been very happy with the performance. I plan to make a number of dual bands. The DBJ antennas seem extremely inexpensive and easy to construct. The price per foot for RG-174 type coax was outrageous locally so I ordered an entire spool of Belden. Another project on my to do list!

Dave

I have an antenna analyzer, an MFJ 259B I purchased a couple of years ago to tune the DC ground .640 omni ground plane I built and run now. It's the best 11 meter omni antenna in existence today bar none.

I'm currently working on the tilt-up tower setup the quad will go on. It will be completed in a day or two.
Once that's completed I can start building the antenna.

Beyond the reflector and the first director, will the second and third director have any effect tuning the antenna?

I don't want to cut up any more copper wire than I have to in order to get this thing tuned.
I plan on using #14 gauge tinned Flew-Weave wire for the loops and it's not cheap.

Keith

4527. Quad and tower

Yahoo group: ham-antennas (2008)
Date: 2008-03-30 05:17:17 UTC
From: richard erickson
Topic: 4453 Message: 4527

I'm currently working on the tilt-up tower setup the
quad will go on. It will be completed in a day or two.
Once that's completed I can start building the
antenna.
****
Two points: First, I'd like to know about your tilt up
tower. I'm assuming it is a home brew. I'd like to
know about your design. Could you share a picture.

Secondly, here is a book I have had for a long time.
I found it listed at Amazon.

http://www.amazon.com/All-About-Cubical-Quad-Antennas/dp/B00125L07Y/ref=sr_1_7?ie=UTF8&s=books&qid=1206854047&sr=1-7

They do not have any . . new or used. I have used
this book and continue to use it. Good book.

One thing about quads .. at least my quad . . they are
very forgiving.

Topic: 4453 Message: 4528

Richard

They're out there IF you want to pay the price.
http://www.amazon.com/gp/offer-listing/B0007EX2M2/ref=sr_1_olp_1?
ie=UTF8&s=books&qid=1206886617&sr=8-1

The best price I've found so far is $41.00 plus shipping.

I had several sticks of 2x2" x 1/4" thick steel angle and a 10' x 10'
concrete pad so I built a framework to tilt the tower.
I'll get some photos when completed.

Thanks

Keith

Has any one ever made a J pole beam? You build a J
pole and put a director and a reflecter on it. Any idea
what the gain might be? Good questions for the
people that have computor antenna programs. Thank
you.

4530. Re: Optimize G5RV?

Yahoo group: ham-antennas (2008)
Date: 2008-03-30 17:29:34 UTC
From: frostbitnome
Topic: 4514 Message: 4530

Yesterday I took the antenna ends up to 15' above ground, so it now has much less slope to the legs, or less angle to the ground.
Still performing poorly, no better than it was originally, in fact, I think its noisier. With the 80 meter band "in" last night two hours after dark, a local also with a G5RV three miles from me was working an in-state ham. I could only hear the local, zero copy on the other.
Lots of noise (s9+).

Well, this eliminates the G5RV as the culprit, since a fellow 3 miles away using the same system was doing alright. Possibilities: Poor rxvr front end, lossy coax (run ladder line all the way), lossy antenna tuner? Also just to humor me, try laying a wire counterpoise on ground under the G5RV. Worth a try.

I'm running a G5RV as an inverted V and it now works great. I had the center insulator attached near the apex of the house at 20 ft up and the ends down around 8 ft. I found that if the center insulator is too close to the building however, I get very poor performance. By relocating the antenna so the center insulator is at least 4 ft from any structure the performance improves greatly. Last night I had contacts in Ontario Canada, South Carolina and Florida, all from central California! Just FYI.

You might be better using a bent dipole.
bend the ends, or zig zag, even fold back or in a loop of sorts.
I found that a straight dipole atten feet above ground at the center, and ends barely above ground, worked fairly well when I camped on some desert property I had a few years ago.
Plus where I lived in a trailer park for over a year, I had my 75 meter dipole in an almost delta loop, and not all that high. Main thing is to have the full length wire there, even if you have to bend it around to fit the space.
An antenna that is not full length for the band will perform less well. this includes receive as well as transmit.
When I added 75 meter legs to my 40/20 dipole, it improved both my ougoing signal and my receive. I had been using a tuner to work 75 using the 40/20 dipole. It was like adding an amp on TX and a preamp on RX when I added the 75 meter legs. And I had those bent so it was only above the roof of the mobile home I used to live in.
bending the ends around should, IMO, work better than using loading coils.
Plus you can "tune" the antenna so that you have at least some parts of the band you can work without a tuner. This means adjusting the length. I always started long and removed wire to get where I wanted it.
The G5RV requires a tuner, period.
A dipole can be cut so it can be used without a tuner for part of the band.
YMMV

A G5RV has to be up at least 32.6 feet so the 450 ohm ladder line is suspened 90 degrees from the 102 feet horizontal line.

The G5RV likes to be bent down inverted vee fashion by 120 degrees only.

The G5RV also likes a tuner.

The G5RV also like at least 100 feet of coax

Mine is up only 19 ft and the ladder line drops straight for 10 ft and
then loops twice before reaching the coax. It works great.

The ARRL has a great deal of reference material on this antenna and
many others as well, Google has info also, just an adjunct!

4537. Coax Question

Yahoo group: ham-antennas (2008)
Date: 2008-03-31 18:23:36 UTC
From: Ross
Topic: 4537 Message: 4537

I have about 30 feet of extra RG8U coax coiled under my desk for HF. The total run to the antenna is about 60 feet. I also do this with RG58U for my UHF/VHF antenna.

Some people have told me that this is not a problem, while others tell me I have created an RF choke that would have a large impact on my power. I like to have this spare coax so it allows me flexibility of moving my setup around. I have found that I start ending up with shorter and shorter coax as I keep cutting it up to serve my different purposes.

Ross

Coiled-up coax should have no effect at all on the signal being carried inside the coax, which is where the signal generally ought to be. But there can also be common-mode currents, which flow on the outside of the coax, and they radiate from the coax just like an antenna. This is usually considered undesirable and is to be avoided, but sometimes it is not so bad and there are HF antennas that actually make use of signal radiated from the feedline.

Coiling up your coax does indeed form a choke that impedes these common-mode currents, and this is usually considered a Good Thing (except for those antennas that want the coax to radiate). You will not be losing any power because of that. Those that say it impedes the signal inside the coax don't understand how coax works.

Maybe a bigger problem with a lot of extra coax, is the coax loss, esp. at UHF/VHF. This loss is there whether or not the coax is coiled up.

Andy

4539. RE: [ham-antennas] (Coiled-up) Coax Question

From: Kirk Morrison
Topic: 4538 Message: 4539

Andy is correct, it forms a common mode choke and acts as a balun more or less. I have one at my antenna switch, and all it does is basically it helps prevent TVI in my house. Before I used it I had a small amount of RF on some bands in the house, afterwards, not so much, but I later added by low pass filter and got rid of all of it. I used 7 turns in a 8 inch circle of RG 8X don't do it to tight or the conductors can shift over time. This is a recommended practice except at VHF and UHF, by a lot of authors, so it isn't a bad thing to do, if you have the coax and don't want to buy a slightly lower loss Balun, don't worry about the losses. Unless you are at 28 MHZ or above using 58, 8(X) or 213 I wouldn't worry to much about the losses from an extra 10 or 12 foot above that I might, depending on the frequency and they coax.

From: frostbitnome
Topic: 4514 Message: 4540

I have a tuner on it. AT100pro, radio is a Yaesu FT857D. It has 30
feet of ladder line, then 70 feet of coax (equals 100'...its one of
Kerry WAWNAN's units...the reviews on eham are stellar)
I took the antenna down last night and took it to a large open field
free of any obstructions. It was quiet. It just does not like my house
location, I guess. It will remain down until I figure out what to do
next, which may be sell off the brand new HF gear and stay with
UHF/VHF, where I have been 11 years. I thought my HF upgrade was going
to be fun...not the case.

It sounds to me like you have a RF noise issue at the house, not an antenna problem. Try unplugging everything you can in the house, or turning off breakers one-by-one, to see if it suddenly stops.

The usual culprits are wall wart power supplies, dimmer lamps, florescent fixtures, but it could be almost anything. It could also be outside your house, but coming in via the power lines.

There are a lot of resources on RFI issues and tracking down problem sources. Unfortunately it's sometimes required to make a QTH usable on HF, but it's worth the effort.

Hope this helps - don't give up on your new gear!

73,
- Dave

Let me see, you are using RG8 for your HF antenna, okay, not a problem,
nor shooulfd the 30 feet coiled up be a problem.
But you say you are using RG58 for VHF/UHF. That is so lossy, that it
loses a lot at only 15 feet or less, especially on the 70 centimeter band.
As an example of losses at 442 MHz, I have tested two seemingly identical
100 foot sections of RG8 from Cable Experts, factory assembled. One, with
60 watts being fed to it at 441.950 MHz, showed maybe 1 watt at the end.
The other was a bit better, about 4 watts.
That gives you an idea of the loss/attenuation of RG8 at UHF frequencies.
RG58 is going to lose far more. You'd have been better to use RG58 on HF
and the RG8 on the VHF/UHF antenna.
YMMV

So what would be a practical coax(cost,availability,installation,etc) for
UHF use? RG6 TV coax?

Phil,

You might want to think about any of the big players low loss 8U type coax:
RG/8U, 9913, etc.

You may want to use this calculator to explore different coax and figure
out how much loss you can live with. <www.ocarc.ca/coax.htm>

Those who walk bravely through life, unafraid of loss or failure,
find that they very rarely lose or fail.

4546. Re: [ham-antennas] Coax Question

Topic: 4537 Message: 4546

It becomes difficult. I used RG8 connected to my J pole, as well as to my 2 meter beam (which also worked on the 440 band). But the loss was acceptable, being as I mainly talked through repeaters.
RG6 would be a fair idea, but you would need adapters, being as connectors other than "F" type are hard to locate for RG6 types. OTOH, it is readily available, but would be low power. I would have to look up the power handling capability of RG6. And remember, RG6 is basically 75 ohm cable, where most radios are designed for 50 ohm cable.
Heliax would be great, but not as inexpensive. OTOH, I bought 100 feet of 7/8" Heliax for about $2.50 per foot, plus "N" connectors at about $20-25 each. PL259 type for Heliax ar even more costly. And heliax is not good for a rotatable beam. You'd need a bit of something readily flexible for that.
RG8 in shorter lengths can do a fairly decent job. Use only the amount needed for the job.
I have been doing some testing for my repeater for temporary use, and found out just how much loss I evidently had. Putting losses in terms of watts in VS watts out shows one far better than simply saying X.xx Db loss per 100 feet at XXX.00 Mhz.
I have been using a Bird 43 Wattmeter and testing into a dummy load made for use up to 500 MHz or so.

Anyway, it is a matter of using what you can at a reasonable cost and accepting the losses that will be involved.
You will maybe get all kinds of suggestions about what cables to use.
If you only need 25 feet from the radio to the antenna, then only use that amount of cable with just enough added length to work comfortably in your situation. I will be cutting part of my RG8 to a shorter length for what I want here, till I get things settled and install part of the Heliax I have. It will have a very low loss compared to the RG8.
YMMV

All good info-Thanks,all.
My background is consumer electronics and home Tv antenna systems. Here's a radical alternative: I know the old "flat lead" 300 ohm was wonderful for UHF TV reception,as it was very low loss,tho it took special installation. How bout with a long run, use 300 or 400 ohm flat line for the long UHF run out the shack and up the tower, with a balun up top to convert back to 50 ohms for the antenna with a short coax. Practically no loss compared to coax, and the recieve should have negligable losses, too. Not as "neat" as coax.

Phil,

You might want to think about any of the big players low loss 8U type coax:
RG/8U, 9913, etc.

About 30 plus years ago I did that using what they called "color tv antenna wire" which was 300 ohm twin lead with a foil sheld. Then I built a coax balun for each end and used it on my two meter beam that I had up at the time it worked great. I had this up for a cople of years with no problems.

4550. Re: [ham-antennas] Coax Question

Yahoo group: ham-antennas (2008)
Date: 2008-04-01 18:02:39 UTC
From: Wayne
Topic: 4537 Message: 4550

Doing a bit of searching gives me a better handle on the possible losses.
In what is considered RG8 type coax, Belden 9913 and LMR 400 are the two lowest.
This is figuring 100 feet and an SWR of 1.5 to 1 at 450 MHz.
RG6, while lower loss than RG58, does not fare as well at that lengrh.
1/2" heliax is even better. The latter can be bought for $1.45 per foot, however, UHF (PL259 type) connectors will run aabout $45.00 each. "N" connectors will run about $14.00 each. To calculate cable losses, see:
<http://www.ocarc.ca/coax.htm>
The Heliax is available from: <http://www.surpluscoax.com/index.html>
Note that it is advisable to buy the connectors at the same time that you buy the cable.
And connectors tend to be specific for each type of heliax/hardline.
Even some of the "regular" coaxial cables may require a special connector.
I had a bear of a time putting PL259's on some 9913F7, as the center conductor is stranded, and is actually a bit too large to fit the center pin.

As I said before, calculate possible losses, and figure that the amount/percentage of loss on TX is also a clue to the loss on receive. The lower the loss, the better.
A numer of repeaters are mounted in cabinets on the tower the antenna is on to keep the feedline losses down.
With virtually any type of coaxial cable, the shorter the run, the better.
This means, on 2 meters and higher, do not use much more than 5 feet above the length needed to keep losses to a minimum.
On HF, ten meters and below, the loss is not enough to make a huge difference. But what yu might need to think about is the amountof powr the cable can handle. While RG58 can handle 100 to 150 or 200 watts on HF, 500 watts or more could cause some serious problems. Center conductor getting warm enough to start melting the insulation, and this in turn creates more problems. At 100 to maybe 120 watts (the average for most HF transceivers, depending on the supply voltage) RG58 is no problem I have used RG58, as well as Mini 8, also called 8X, and am presently using RG 8 mainly because I had it handy when I put the antenna up here. But I am thinking about taking it down and using another chunk of cable so I can test that chunk on the 440 band.
I have a 2 element beam for 2 meters up, and it has maybe 50 feet of 9913 F7 running to it.
Loss acceptable for that band.
You do need to calculate for the brand of cable, as well as the type. But unbranded cable can be an unknown. The Cable Experts that I have only says cable Experts type RG8/U and is not found on tha calculators out there.
And I see a good deal of difference in loss between two supposedly idenitcal cables.

Once again, calculate your losses and take it from there.

N to UHF adapters are much less than the difference in price. my 2 cents.

Shielded 300 ohm twinlead has some pros and cons compared to ordinary unshielded twinlead.

Unshielded twinlead, when dry, is theoretically better because much of the dielectric is air. Air is very low-loss. Ladderline is even better. Shielded twinlead confines the energy to plastic instead of air, so it is somewhat higher loss.

On the other hand, shielded twinlead can be better than unshielded in that the loss doesn't go up when it gets wet (assuming that the moisture stays out of its insides). And it is easier to install, no need to worry about running past metal.

Andy

How did this turn out, and what figures did you come up with?

P-in vs P-out? Was it a "reasonable" loss, or was it more/less than you thought?

With the traditional 300 ohm "TV" twin lead,(or any unshielded twin lead) it does require some special handling. You use stand off insulators to hold it in place going down the mast, staying away from metal. You want the lead to have a twist to it, usually about one revolution per 1-2 feet. This tends to null any signal hitting the downlead directly. With TV,(and FM broadcast) it helps cure "multipath", where a station's signal hits the lead and the antenna, and hits the reciever a few microseconds apart. I guess, the whole thing with any transmission line is a trade off:Does using the extra coax get the antenna heigth high enough that the increased signal strength offsets the line loss to acheive it.
Best,
Phil B

True, the most common adapter being N male on one end and UHF female on the other.
I have been using one on my dummy load for years.
But they are not as easy to find as other items at times.
And not to be found at your local CB/Truckstop place, ah ha ha.
But can be found if one searches. Radio Shack stores used to carry the N Male UHF female, but many rat shacks are carrying less and less. Items in stock vary a lot from one store to another.

yes, it would be a lot cheaper, if buying Heliax, to buy the N connectors and use adapters as needed.
My dual band Diamond X510NJ has the N connector, though due to the base of the antenna being a bit too small, I had to install a short 1/2 heliax jumper, and will connect that to the 7/8" using a double female. I stocked up on these items from Ebay, at a reasonable price. 7/8" Heliax connectors are massive, so cannot be used directly in some instances. But those for 1/2" heliax should fit most antennas.
I plan for as low a loss as possible to get the best range possible.

BTW, the Amateur Radio handbooks used to have information showing how to install coax connectors, including N and BNC types. This was basically for RG8 and RG58 type cable.

Also, N connectors are supposed to be lower loss than UHF connectors at higher frequencies.
I should put a picture of the end of my 7/8" heliax on the groups photos so people can see what the construction is like. Shielding it 100%, being as it is a sort of corrugated copper tubing, and with the larger sizes, the center conductor is actually tubing. The center pin for the Heliax N connectors actually threads into the center conductor. No soldering or crimpng...

The loss with the particular RG8 coax is greater than I had thought.
Actually, one piece is so bad that it is pathetic. The other is useable, though still higher than I had anticipated.
Going by the calculator, it has greater loss than RG8X/Mini 8.
Not all coax is as good as it supposedly should be.
When I cut the one chunk, I will be putting an N connector on the cut end.
I had posted about the loss with Cable experts RG8, and found that others have had poor results. In one instance, it was because the connector had been badly installed.
At any rate, I will never buy any of their cable again
Power in VS power out shows a horrible loss compared with what it should be.
Should be about 70 watts in, and getting about 3.5 watts out at this point with the better of the two cables. I may use it for HF only once I get my Heliax installed...
hate to waste an N connector on the stuff.
I could use some 9913F7 I have, but there is a potential noise problem running full duplex with This type of cable (foil inner shield and braided outer shield).
YMMV

It sounds to me like you have a RF noise issue at the house, not an antenna problem. Try unplugging everything you can in the house, or turning off breakers one-by-one, to see if it suddenly stops.

The usual culprits are wall wart power supplies, dimmer lamps, florescent fixtures, but it could be almost anything. It could also be outside your house, but coming in via the power lines.

There are a lot of resources on RFI issues and tracking down problem sources. Unfortunately it's sometimes required to make a QTH usable on HF, but it's worth the effort.

Hope this helps - don't give up on your new gear!

4561. Putting up 2nd Dipole - Different direction/orientation

Yahoo group: ham-antennas (2008)
Date: 2008-04-04 21:51:44 UTC
From: John P.
Topic: 4561 Message: 4561

I currently have a fan dipole (75, 40, & 20 meters) that is up about 35-40 feet and broadside East-West.

I am planning to put up a second fan dipole (20, 15 meters) with a North-South broadside.

My question is locating the dipole with respect to the existing dipole.

Due to limitations on where I can place it (trees for support, feed line distance from house, etc.) I am thinking of putting it below (about 10 feet) the existing dipole. I realize that there is some interaction. I am wondering what others have discovered from their experiences. Also can it be directly below the existing dipole or what. How close is too close.

Thanks

Hi all-

I'm a ham returning after allowing my license to lapse. I've been away for a while. This is my first time licensed as a General (former Tech).

My interests this time around are HF propagation and wire antennas.

I'm getting ready to build a fan dipole, but until then I'm using an indoor random wire for receive-only, with a old Kenwood TS-530S.

My question:
Where are we in the solar cycle? I can't seem to find out. My question stems from what appears to be weak reception on the TS-530S. I'm sure an indoor random isn't a good solution, but I remember finding more signals with a random wire and old tube SWL radios years ago.

Depending on who you listen to, we are either at the very bottom or just climbing out of the very bottom. My take (totally unscientific) is the latter. Signals seem to be a little better now than they were this time last year.

BTW - with that call I can guess you are not a CW Contester - wow what a keyfull that is .

James,

We are at the transition point between cycle 23 and cycle 24. We have long periods, 30 days or more, of no sun spots and the SFI hovers around 70. By all reports, we shoud begin seeing sun spots from cycle 24 someting this fall and by the summer of 2009, we should begin seeing increasing numbers of sunspots with a corresponding increase in SFI and propagation improvements.

I use SpaceWeather.com http://www.spaceweather.com to check daily sunspot numbers.

A program for your computer, VOAProp, originally developed as a propagation prediction tool for Voice of America, is usefuld to see where propagation is likely to go for any given month. It has power levels reflecting amateru radio limits, QRP to Legal Limit.

Eventhough we are at solar minimum, there is lots of good DX to be had. This past tuesday, I worked SY8JZ, Mount Athos, Greece, from Arizona running 100w and a vertical.

Welcome back and be patient, better times are coming.

John,

My experiments demonstrate that dipoles that are 90 degrees to each other hardly see each other.

I'd say that you are safe to build it.

Can you put up something temporary to check before building something more robust?

Cheers,

Callum McCormick

From: John P.
Topic: 4561 Message: 4569

You are correct that the antennas will be 90 degrees oriented. As I also said I am thinking of placing it "almost" directly below the existing dipole - down about 10 ft lower.

Also, due to convenience, I am wondering if there might be any other interaction if it were offset slightly to the west - that is the center of the new dipole would be about 10 feet West (and of course 10 feet below) the center of the other dipole. Different feedlines (RG-8X) of course!!

I can always throw it up and see if there is any de-tuning of the existing dipole.

I do not want to foul up what I do have. I get out very well east and west and quite good to the south - note that the North end of the existing dipole is about 15 feet higher than the South end.

Callum M0MCX <callum@...> wrote:
John,

My experiments demonstrate that dipoles that are 90 degrees to each other hardly see each other.

I'd say that you are safe to build it.

Can you put up something temporary to check before building something more robust?

Cheers,

Callum McCormick

Subject: [ham-antennas] Putting up 2nd Dipole - Different direction/orientation

I currently have a fan dipole (75, 40, & 20 meters) that is up about 35-40 feet and broadside East-West.

I am planning to put up a second fan dipole (20, 15 meters) with a North-South broadside.

My question is locating the dipole with respect to the existing dipole.

Due to limitations on where I can place it (trees for support, feed line distance from house, etc.) I am thinking of putting it below (about 10 feet) the existing dipole. I realize that there is some interaction. I am

wondering what others have discovered from their experiences. Also can it be directly below the existing dipole or what. How close is too close.

Thanks

I would tie both old and new to the same feedpoint and see. Like a fan dipole, but at right angles. I bet it would work well. Why seperate coaxes?

From: Phil Bader
Topic: 4572 Message: 4572

I closed my business of 30 years a few years ago. I still stocked a number of aluminum 11 meter antennas (Antenna Specialists). Some are Yagi 5 element beams, maybe a few 4 element, and some others. Was wondering if it was practical to modify these for 10 meter use? One would need to change the gama match setting, spacing of the elements on the boom, as well as the element lengths. Wonder if it's worth the hassle. Maybe borrow demensions from a 10 meter beam?
Also have a few Larsen base ground plane 450-470 business band antennsa. Close to the 440 ham band.

Hello Phil - Very practical and has been done numerous times - I am
using one on 6 meters right not that was copied very closely to a 5
element that was produced by Cushcraft - It is one of the best antennas
I have used for 6 ever, very nice pattern and no big holes in the side or
rear - I have another that I wish to get airbourne soon that is a 6 element
with both vertical and horizontal polarization - I hope to use the vertical
for FM on 52.5 approx. and the horizontal down on SSB at around 50.250.
Have often thought about building it with 6 meter vertical and 10 meter
horizontal or as a dual band if you will but decided that would be for
another day - another tower.
If I can be of any help on your layout I have a lot of different Yagi programs
that would get you going. Actually, you probably won't have to change the
gamma assy. hardly at all. Just the element lengths primarily -
73 de N?ATH / Dave

Yes, did one back in the 80's (5 element hygain long john). First, I made it for 10 meters with the 5 elements and it work fantastic. After 10 starting going down I made it into a 3 element 15 meter beam and worked great for several more years. I bought a tribander and retired the converted beam, but it was the most powerful beam I ever had for 10 or 15. Wish I had another one to do..go for it and enjoy, 73 Alan

From: John P.
Topic: 4561 Message: 4576

You are mostly correct.....

There will be
East-West broadside orientation
1 for 75 meters
1 for 40 meters
1 for 20 meters

North-South broadside orientation
1 for 20 meters
1 for 15 meters

Note that there will be 2 for 20 meters AND a 3/2 wave for 15 meters (40 meter element) and a 1/2 wave for 15 meters.

Thus connecting them all to the common feedpoint could be "interesting" to say the least with regard to SWR, resonance, feedpoint impedance, and radiation pattern.

Thinking about this.. and only for the 20m band, if you did happen to make a "cross" of dipoles on the same frequency at right angles to each other on the same feedpoint, a few things would happen including splitting your power across two antennas, inability to switch directions and the impedance will drop from around 80 ohms to 40 for that band.

I didn't know about the impedance issue until I modelled it!

Suggest you don't do that with same band then :)

Callum

From: Wayne
Topic: 4561 Message: 4578

You are correct in that having a cross shaped dipole (would one call it something else?), that the signal would be split between the two legs.
Now, the impedence going to 40 ohms would not be a problem, considering the radios are designed for 50 ohms. A 1/4 wave mobile whip supposedly has an impedence of about 30 ohms, theory and practice are not always exactly the same, and was normally not a problem.
The directional part is the major issue from what I can see. Shaped into a cross like that, would make it more omnidirectional than a straight dipole, at least under ideal conditions.
I consider that to be the major issue here.
Adding legs to a multiple dipole does change the resonant frequency. The amount depends on a number of factors, such as how close to one another do the legs ru.
I had a 40 meter dipole that I added 20 meter legs to. Was fairly good on 40 meters, and a good match on 20. But after I added 75 meter legs, it changed to where the resonant frequencies were actually out of band on all but 75. One needs to consider the interaction there.
As an example, if I added wires to my 75 meter portion of my present 160/75 dipole, and they were out near the ends, I would widen the part that would be resonant enough to use sans tuner.
I may do just that one of these days, and at the same time, trim back the 160 meter legs, being as those are actually too long at this point. Tuner takes care of it reasonably enough, so I'm not in a hurry right now. Don't feel like wading through the tall dried weeds...

Anyway, having a more omni antenna can be good in some ways, and not so good in others.
YMMV

Your thinking is good!

My current fan dipole for 75, 40 & 20 has good SWR on 75, 40, & 20. Not too good though on 15 but workable.

My primary purpose of the 2nd fan dipole for 20 & 15 is to get a North-South broadside. Remember that the current one is broadside East-West (90 degrees/180 degrees). My thinking is separate feed lines wich is not a problem. My only concern would be the resonant lengths in proximity (but @ 90 degrees offest) to the current fan dipole.

If you drove two *identical* dipoles in parallel from the same feedline, then the signal would split equally between the two. But if they aren't identical, then one would get more power than the other. It depends on how each of their feedpoint impedances happen to work out.

It seems to me that putting two dipoles at right angles, with the same feed, does not give you an omnidirectional radiation pattern. What you'd have is an X component and a Y component, and if the two are in-phase, they are equivalent to a single dipole at 45 degrees, with a figure-8 pattern at a 45 degree angle: nulls going NW and SE (or NE and SW depending on relative polarities).

Using separate feeds isn't a bad idea, giving you the ability to select either the N-S pattern or the E-W pattern.

Putting a resonant length at right angles, ought to minimize if not eliminate interaction between the elements. In theory each element is at right angles to the radiating fields from the other, so it sees no signal from it, and doesn't interact with it.

Andy,

You have echoed my thinking on this one. My biggest concern was/is the fact that the N-S dipole's legs would be in the MAX lobe of the E-W dipole & vice versa. I would not want to upset the MAX lobes.

Thanks,
John

Using the same feedpoint is a complete red herring.

Just split them and build two of the blighters on different feedpoints. It will work as you plan. Really.

4584. Elevated radials on a GP antenna

Yahoo group: ham-antennas (2008)
Date: 2008-04-06 20:34:06 UTC
From: Neil McGrath
Topic: 4584 Message: 4584

I currently use a nest of 1/4 wave verticals on 10/15/20m at ground level connected to a ground rod and a few buried radials. I have heard that using a 1/4 wave counterpoise a couple of feet above the ground could be more efficient. Does anyone have any experience with this type of set up.

I moved my HF9V, 80-10 meter vertical from ground-mounted to about 12 feet high, and put tuned 1/4-wave radials for each of 80/40/20 meters under it. Based on how quickly I get through pile-ups now, I'd say I increased my signal strength 8-10dB on 80 and 40 meters, and 6dB on 20 meters. Also did some A/B comparisons with a high dipole, but since the dipole is horizontal, the results from that are not all that reliable - but again, the vertical's performance for DX took a dramatic step upward when I removed it from the ground (where it did have some radials, some long and some short, none really tuned). For short-distance QSOs, my dipoles have always beat the vertical.

4586. Hy-Gain beam

Yahoo group: ham-antennas (2008)
Date: 2008-04-07 00:23:03 UTC
From: Kenny Wyss
Topic: 4586 Message: 4586

I am getting ready to put up my first tower and plan to use Rohn 25G and only go about 30' for now. I am in the process of cleaning and tweaking my HF beam in order to use it for the first time. The ham I bought it from said it was a Cushcraft A3S, but I am not sure. It has a Hy-Gain balun mounted on the boom and does not match the pics of a Cushcraft. It has two thin-wall pipes mounted on top of the boom also that sort of remind you of a double-barrel shotgun.

Does anyone have any ideas as to what the model number of this beast could be? I would love to find the correct manual and specs.

Thanks and 73,

Kenny, KB0NPW

Dave, that would be much appreciated if you have it. After reading your reply, I Googled the TH3 and found pics of the TH-3MK3 and that is the one I have. I am so glad to know what I'm working with now. I plan to take each element apart and clean the contact surfaces. I hope the balun is still okay. It had a lot of gunk and cobwebs inside.

Thanks and 73, Kenny

Kenny,
If the balun is too bad and you plan on running low power let me know as I have a BN-86 around here somewhere I will let you have inexpensively. I bought it before I got my amp and it ended up excess.

4590. Re: Putting up 2nd Dipole - Different direction/orientation

Yahoo group: ham-antennas (2008)
Date: 2008-04-07 02:03:53 UTC
From: Brian Hall
Topic: 4561 Message: 4590

If you are trying to get rid of the north-south lull, why not droop the ends of your existing antenna into an Inverted Vee configuration? That will make the radiation pattern more omni-directional.

In order to have any substantial gain (a broadside lobe in this case), your dipole should be elevated at least a half wavelength or higher at the frequency of interest. If I read your first post correctly, your proposed antenna will be even lower than the existing antenna, so I question whether or not it's a worthwhile addition.

I'd recommend changing to an inverted vee first before trying something else.

4591. Suggestions for dipole supports

Yahoo group: ham-antennas (2008)
Date: 2008-04-07 02:39:54 UTC
From: James Fogg
Topic: 4591 Message: 4591

I'm trying to think of a good support for either the center of an inverted V or end supports for a flat top. I'm looking for support from the ground up to 20 or more feet.

What do others use? Is metal pipe a poor choice? Does PVC have enough strength at 20 plus feet?

My situation is my trees are too far away for anything shorter than an 80M dipole. Even a 160M dipole doesn't reach my trees.

James,

I buy gov surplus aluminum mast sections from www.tmastco.com and simply
love the stuff. Henry is a good guy.

They make the 4 foot Military sections in PVC also, they are strong and easy to put up, of course you probably would have to guy them at 2 points, the antenna being the third.

Brian,

First of all, thanks for your input.

The current dipole is about 40-45 feet up which on 20 meters is just over 1/2 wave length up.

Ths second one would be at about 30 feet - just shy of 1/2 WL.

An inverted V is not practical in order to be sure that the ends are far above the line of sight of the property.

Thus the practical solution is the 2nd dipole

Thanks

Brian Hall <bnhall_2000@...> wrote:
If you are trying to get rid of the north-south lull, why not droop the ends of your existing antenna into an Inverted Vee configuration? That will make the radiation pattern more omni-directional.

In order to have any substantial gain (a broadside lobe in this case), your dipole should be elevated at least a half wavelength or higher at the frequency of interest. If I read your first post correctly, your proposed antenna will be even lower than the existing antenna, so I question whether or not it's a worthwhile addition.

I'd recommend changing to an inverted vee first before trying something else.

Jim,

Forgot to mention that a fan dipole for 75/80, 40, & 20 would work for you since you say that you have room for an 80 or 160 meter dipole.

My fan dipole for 75, 40, & 20 has its ends near the sides of my lot AND my lot is 225 ft wide!

4598. Alpha Delta Antenna

Yahoo group: ham-antennas (2008)
Date: 2008-04-07 22:54:06 UTC
From: Bill Reid
Topic: 4598 Message: 4598

I purchased an Alpha Delta-LB Plus and installed it this past weekend.
It tunes fine on all bands except 160M. I'm using a FT100D radio
and a LDG AT-200Pro antenna tuner.

I put a spectrum analyzer on it in reflection mode and it shows the least
reflection around 1.76Mhz. I would have thought that the tuner would have
tuned this antenna.
What do I need to do? The instructions are not that good nor is online help.
I'm guessing that I need to shorten the end of the line next to the insulator,
but I was hoping the tuner would do it, as it will be some work to
get at one of the ends.

You may have exceed the 10:1 limit of the tuner. Doesn't take very far
on 160M to hit that much SWR.

Bill,

I have also been playing around with the Alpha Delta -LB antenna mounted in an inverted V configuration and have not been satisfied with the way in works on 160 mtrs. The problem is that the Q is so high on 160 mtrs that the antenna must be installed completely in the clear in order for it to resonate properly on 160 mtrs. In my installation, the feed point of the antenna is just 5 feet above the peak of my roof (approximately 40 ft above ground). The antenna extends across the front and rear slopes of my roof and for 25 feet in both directions, is between 5 and 8 feet at the most above the surface of the roof. This detunes the antenna so much that with a coax feed, I could not get it to load correctly (even with a wide range tuner) even on 75 mtrs. I finally changed the feedline and the center insulator out to a 450 ohm ladder line feed system. I used that very sucessfully into a Dentron MT-2000A tuner for a couple of years. I have now been experimenting with using a 1:1 current balun to transition the ladder line to coax at the entry point to the shack. The Balun is a DX-Engineering unit. That too is working well for 40/75 & 80 mtrs. However, it is very difficult to tune 160 mtrs.

I have a similar antenna installed at our club station at work (Boeing Aerospace, WØMA) and it is mounted in a dipole configuration at 30 foot above a roof which is 40 feet above ground, for a total height of 70 feet. The antenna loads fine on 160 mtrs and is resonant around 1820 khz with the 2:1 SWR bandwidth only about 20 khz ! As I mentioned before, this antenna is a very HI Q design, developing significant current nodes along the antenna. Recently , we literally melted one of the end insulators while running the KW on 160 mtrs !

Good luck, but I think it is very difficult to use a shortened antenna, other than a vertical with a good ground, on 160 mts.

Funny you mention this. I was just running my analyzer on one last night at a friend's house.

160m is fairly narrow on it so he had to go through a tuning cycle for 160m and 80m to get them both where he wanted them. Basically he shortened up the wires a bit and re-checked and repeated a few times.

It's a bit tedious, but we got it right where he wanted it. It was down to 1:1 on 160m where he wanted the center when we were done.

The SWR definitely takes off rapidly once you reach the edge of the tuned segment though so it isn't surprising to me that you had issues if you were trying to tune 1900 or so with your antenna.

I was impressed with it overall, I'd much rather see a narrow range like this on a multi-band as it generally indicates less losses than some of the terminated folded dipole dummy loads.

Take some time and tweak the tuning, start with 160m and work in and do 80m after you get it set, there is interaction between them as you tune so it's a bit annoying, but will pay off.

We were making contacts with 5W from his 817 with it when we were done, so it does radiate pretty well. I managed to snag Canary Islands on 40m PSK with it on 5W.

For 20 feet, I recommend hurricane fence 'top rail' Home Depot sells it for $9.50 for a 10' length locally. I took the slip joints and drilled them and ran sheet metal screws in to set the joint.

It's galvanized so it should hold up reasonably well in the weather.

If you bracket them against a fence post, they will need no guying. I have a 17' vertical on top of 20' of this on the side of my house and it is rock steady in winds I've seen up to 40mph so far.

I'm not sure how 30' of them will hold up....but I'm getting curious as I'd like to use two 30' setups as back supports for a loop here.

You'll want a few feet distance from the ends of the dipoles so they won't affect the tuning.

From: Paul
Topic: 4561 Message: 4603

All kinds of stuff can happen...

If the two dipoles are properly spaced and the phase angle is
correct, the resulting array will be directional "straight up" !!!
with circular polarization...

This is not all bad; on 40 and 60 meters it would be GREAT for NVIS.

From: Keith
Topic: 4453 Message: 4604

Callum

I'm running a 23' vertical .640 DC ground version of the Avanti Sigma I built.
It works quite well considering it's location and elevation.
The only part on it that I didn't make is the hub for the ground radials.
It's a cast aluminum hub that is the weakest link, most problematic part of the antenna.
The hub issue will be addressed and fixed when I get the time and after the best resolve pops into my head.
It survived high winds that took out about every factory built antenna in this area.
It was really quiet around here after that storm until they all put up new antennas.
The wind was so strong it ripped shingles from the roofs but my antenna survived.
It has to, it's so close to high voltage power lines it can't blow over.
If it did the push-up pole mast would come in contact with the power lines so I build things to stay put.
It has a dual tuning system, one to tune the electrical length and the other to tune the DC ground side.
I tuned it with an electrical 1/4 WL of coax and my MFJ antenna analyzer.

Enough about that, my main intent was about your reply.

When you say "1/4 wave stub" are you referring to an electrical 1/4 WL of 75 ohm coax?
Just want to make sure we're on the same page here.

"Work out the natural impedance then match it afterwards"

Not sure what you mean there.
The loop size matched with the 1/4 WL of 75 ohm coax?
I'm using this quad calc for the wire length loop and spacing.
http://signalengineering.com/ultimate/4_element_quad.html

Is that calc good for loop size and spacing?

Why is it that the driven loop on a quad is always longer than a full wave length no matter which quad calc is used?
What am I missing there?

More severe weather approaching so it's time to go, the lightning is getting closer.

Thanks

Keith

4605. MFJ969 versa tuner II

Yahoo group: ham-antennas (2008)
Date: 2008-04-09 08:11:00 UTC
From: vk2pws
Topic: 4605 Message: 4605

Hi all,
Newbie to the group. I just picked up a pre-loved MFJ969 versa tuner with roller inductor. I've lifted the lid like you do to make sure everything is intack or not burnt out especially the baluns. The inductor appears clear of any corrosion as does the roller.

The question here is, is there anything on the market to clean the inductor or roller as I want to make sure I have a prefect electrical connection between the two.

Regards
Wayne VK2PWS

4606. Re: MFJ969 versa tuner II

From: Dana Elliott
Topic: 4605 Message: 4606

I have this tuner also. What I use is silver cleaner. I buy mine from Walmart or simular store in the jewelry section. It's a liquid. I wet a small towel corner and turn the inductor while holding the wet towel against the inductor.

Watch out for the soldered ends they like to eat the towel. The spring loaded roller is sharp but it needs cleaning as well.

That's how I do it. This tuner is prone to need cleaning every six months or so. Your milage may vary.

Dana - KR7P (new call since we moved to seven land)

4607. Satellite Antenna motion range

Yahoo group: ham-antennas (2008)
Date: 2008-04-09 18:47:08 UTC
From: wizhippo
Topic: 4607 Message: 4607

I am making a portable lightweigt satellite anttena and tracking system.

I am making the antenna's according to the amsat cheap antenna designs using laminated foam board for the booms.

What I am interested in is what range of movement is normally needed during a satellite pass?

For example do I need more then 90deg elevation and 180deg azimuth of movement during a single pass?

If this is the wrong groups to ask this in please direct me to the correct one.

4608. Re: Satellite Antenna motion range

From: James Hickox
Topic: 4607 Message: 4608

Many old timers used to mount their antennas with about a 20-30 degree elevation to the horizon and fix the antenns at that position, allowing them to only track in azimuth. I have used this idea also with good results. You may find that there are very few passes when a LEO bird is high enough to warrant a 90 degree elevation.

By the way, just using an azimuth tracking system can be very inexpensive and workable with older hardware. Do a web search for "a ptractcle rotor system" to get some more ideas.

4609. Mobile - Multiple 2 meter antennas

Yahoo group: ham-antennas (2008)
Date: 2008-04-10 15:28:01 UTC
From: N3UJJ (Scott Gillis)
Topic: 4609 Message: 4609

Hello to the Group,

I'm looking for suggestions & feedback on mounting two 2 meter antennas (and a Tarheel II) on top of a Minivan (Toyota Sienna to be exact).

I currently have an IC-2200H that I use for APRS (transmits roughly every 60 seconds), and will be adding an IC-7000 with a diamond Dual band antenna.

I'm concerned about the close proximity of the the antennas with 50 watts output on 2 meters (as well as the 100 watts on HF)

I would be concerned too. A resonant antenna will have much more RF energy appear on it when the neighboring antenna transmits in the same band. Naturally, this occurs in a repeater and the solution is a tuned duplexer array. That wouldn't be ideal since I'd imagine you'd like to transmit on more than one frequency.

At a minimum, each transmitter will cause receiver desense in the other. I don't think it will actually break anything though. It could possibly help if there's an antenna for a different band in between the two 2M antennas, but it won't be enough to prevent desense.

Thanks for the ideas.

I am thing of using some RC servos controlled by my laptop. It will be very light duty. Having the fixed azimuth definatley reduces the complexity.

Soldering anything that is galvanized is child's play. The galvanized coating takes it very well.

After recalling that you can't solder copper pipe to galvanzied pipe
for plumbing, I'm not going to solder to the wire but use clamps instead.

Thanks for the insight.

4616. RE: [ham-antennas] Re: Quad Questions

Yahoo group: ham-antennas (2008)
Date: 2008-04-10 22:10:06 UTC
From: Callum M0MCX
Topic: 4453 Message: 4616

Hi Keith,

Most of us here build stuff and work out afterwards if it worked or not (!).

In your case, it's more difficult - you are rightly trying to get the basic design down on paper before you commit - however there's some element of chicken and egg because even factories build - then test. You will have to do something along the build-then-test route unless you buy a pre-configured system.

The impedance of a quad? I don't know. Build it, then measure it - then match it. That's what I do.

I think I recommended this before - but if you are into vertical gain for 11 meters, I wouldn't build a quad. I really would not. The chances of not getting it absolutely right out-way the possible rewards - and getting it a bit wrong will wreak your gain figures. Building a 4 element vertical yagi on the other hand has a lot going for it. It's basically got lots less risk associated with something going wrong and is easier to match.

I think you'll find that if you want more answers, you'll need to become an antenna experimenter and get the thing singing. But then report back here and tell us what you discovered.

Best I can do right now (half a bottle of wine down and dog tired!!)

Callum McCormick

T: 07976 631881

http://www.m0mcx.co.uk/

While others were busy thinking outside the box, I cut it up because I needed some cardboard for a project I was making.

Subject: [ham-antennas] Re: Quad Questions

Callum

I'm running a 23' vertical .640 DC ground version of the Avanti Sigma I built.
It works quite well considering it's location and elevation.
The only part on it that I didn't make is the hub for the ground radials.

It's a cast aluminum hub that is the weakest link, most problematic part of the antenna.
The hub issue will be addressed and fixed when I get the time and after the best resolve pops into my head.
It survived high winds that took out about every factory built antenna in this area.
It was really quiet around here after that storm until they all put up new antennas.
The wind was so strong it ripped shingles from the roofs but my antenna survived.
It has to, it's so close to high voltage power lines it can't blow over.
If it did the push-up pole mast would come in contact with the power lines so I build things to stay put.
It has a dual tuning system, one to tune the electrical length and the other to tune the DC ground side.
I tuned it with an electrical 1/4 WL of coax and my MFJ antenna analyzer.

Enough about that, my main intent was about your reply.

When you say "1/4 wave stub" are you referring to an electrical 1/4 WL of 75 ohm coax?
Just want to make sure we're on the same page here.

"Work out the natural impedance then match it afterwards"

Not sure what you mean there.
The loop size matched with the 1/4 WL of 75 ohm coax?
I'm using this quad calc for the wire length loop and spacing.
http://signalengineering.com/ultimate/4_element_quad.html

Is that calc good for loop size and spacing?

Why is it that the driven loop on a quad is always longer than a full wave length no matter which quad calc is used?
What am I missing there?

More severe weather approaching so it's time to go, the lightning is getting closer.

Thanks

Keith

The one real problem I have had using fence wire is that often it degrades quickly and you have to clean it or repair it too often to be really useful over more than a couple or three years. Other than that it works fine.

Rich,

Look for kite suppliers. I buy kite string. Now this isn't your usual 500' for 10 cent kite string. The stuff I buy is rated at 450 lb. and is Dacron. You want Dacron because it resists UV. The last role I bought was 500' for $50.00 so it is workable in price.

From: Bill Reid
Topic: 4598 Message: 4623

I shortened the lead on one end slightly and was able to get the
center location to 1.84mhz ,
but my tuner still will not tune it, even right on the center frequency.

I had a thought after reading the most recent post about a request
for support rope.

I am using antenna wire as a support cable instead of rope. It is
connected on the opposite side of the
last insulator to the tree where it is supported. I use wire for
support on both ends of the dipole.

Could there be an interaction causing me not to be able to tune on 160 Meters?

73
Bill
VA3QB

Mon Apr 7, 2008 7:59 pm (PDT)

I purchased an Alpha Delta-LB Plus and installed it this past weekend.
It tunes fine on all bands except 160M. I'm using a FT100D radio
and a LDG AT-200Pro antenna tuner.
I put a spectrum analyzer on it in reflection mode and it shows the least
reflection around 1.76Mhz. I would have thought that the tuner would have
tuned this antenna.
What do I need to do? The instructions are not that good nor is online help.
I'm guessing that I need to shorten the end of the line next to the insulator,
but I was hoping the tuner would do it, as it will be some work to
get at one of the ends.

dick,

most of the group might not agree with this, but i will tell you what i use for support rope, and it aint rope at all. i buy 2000 feet of .080 weedeater line, at walmart for 15 dollars. i think you can pull a truck around with this stuff, haven't broken it yet. won't be effected by sun, etc. i use crimp on sleeves to couple it or double it back on itself and tie.

give it a try.
mike

4627. question...

Yahoo group: ham-antennas (2008)
Date: 2008-04-13 01:51:11 UTC
From: Ken Snipes
Topic: 4627 Message: 4627

Since I moved to the hills of Tn, I see the mountain behind me might be a bit of a problem....but since I have a lot of trees behind me, some over 100 ft, I'm thinking of getting a 2 meter 5/8 wave ground plane from lakeview.com , it's rather light weight and i could mount it on a 5 or 10 ft piece of pipe and tie it to tree.....

any advice pros or cons ?? I figure it might get me over this hill behind me a little better

Thanks for all your help

From: James Fogg
Topic: 4627 Message: 4628

Check out google maps and choose the terrain view. It should give you an idea of what you need for altitude to get to a certain destination. Are you sure there's anything behind the hills that you want to talk to? You might try hiking up to the top with an HT and seeing what you hit.

4630. windom

Yahoo group: ham-antennas (2008)
Date: 2008-04-14 01:31:41 UTC
From: ki4mga
Topic: 4630 Message: 4630

Gentleman:

I am fairly new to hf and antennas, and was wondering what would be
the results of a double length windom antenna? It would be cut for 160 m.
One leg would be 354 feet and the other would be 177.
I am open for any changes that would make this better for all purpose use.
It would be my second antenna, my first being a gap titan.

4631. RE: [ham-antennas] windom

Yahoo group: ham-antennas (2008)
Date: 2008-04-14 03:27:56 UTC
From: James Fogg
Topic: 4630 Message: 4631

Are you taking the dimensions for a Windom and simply doubling them? If that's what you're doing you'll change your feedpoint impedance considerably (in a bad way). I've never used a Windom and haven't studied their theory, but doubling most wire antenna lengths is a bad idea.

For "all purpose" use, an inverted V is a nice design. If you can achieve the height needed for a 160M inverted V you'll have an antenna with an almost omni directional pattern that you can use on other bands with a tuner.

From: Kd0zz
Topic: 4632 Message: 4632

Good day gentlemen. I just joined the group and was looking through pastposts. I am setting up a cage vertical on 20m and was wondering if Neil , G7AQK has any more comments on his set up. The feed point of the vertical will be 30' up with 18 radials, dropped approx 45 degrees to give 50 ohms. The vertical is a 4.5" diameter cage.

4633. hf and 2 meter questions

Yahoo group: ham-antennas (2008)
Date: 2008-04-14 15:29:35 UTC
From: peglegkd5gyg
Topic: 4633 Message: 4633

Putting up a tower but to the east of my house I will not be able to clear the trees with the direction antenna. on hf how much does this effect your signal.

also I plan on mounting my hf beam on top and thought that I might mount a 2 meter direction antenna below, I have a couple yagi's that need to be hung somewhere. I how close to the HF antenna can it be before it will have an impact on it and the hf antenna. I plan on putting up some kind of multi band beam for hf.

thanks

Rich,

If this is a tuned and elevated radial system for a single band, you shouldn't need more than 2 (officially) and 8 (if you're like me) radials. I found no difference at all when I added more radials to an elevated system.

(ready to be shot down..!)

Just a thought.

4635. VHF mag mount

Yahoo group: ham-antennas (2008)
Date: 2008-04-14 15:36:00 UTC
From: Callum M0MCX
Topic: 4635 Message: 4635

Can someone help me? What is the connector that is normally used on a magnetic mount for VHF / UHF? It's not an SO259. I can't work it out.

I have a very strong stainless N type stud mounted on a quarter inch thick steel roof and I want to buy some sort of change-over connector to mount a small VHF antenna directly to it.

?

Callum McCormick

<http://www.m0mcx.co.uk/> http://www.m0mcx.co.uk/

While others were busy thinking outside the box, I cut it up because I needed some cardboard for a project I was making.

If it is not UHF, then there are a few possibilities. Are you referring to BNC? PL259?

Can you go to Google images and do some research there? Sometimes seeing it is better than describing it.

You are correct. There is a difference, but marginal. The standard is 3-4 here in the USA.

4639. Re: [ham-antennas] hf and 2 meter questions

Yahoo group: ham-antennas (2008)
Date: 2008-04-14 21:08:34 UTC
From: Phil Bader
Topic: 4633 Message: 4639

Why would you mount the smaller 2 meter beam below the larger HF antenna???
I would have a nice vertical,say, 10 meter at top, then a 2 mtr beam with the HF beam (I assume beam,as you refer to a "direction antenna") below. Nice and neat. Still got room at the apex for a nice sloper, inverted V,etc.

4649. Hello Everybody. I have some nice old antennas...!

Yahoo group: ham-antennas (2008)
Date: 2008-04-15 17:15:57 UTC
From: Chris Moore
Topic: 4649 Message: 4649

Well new to the forum I am and also into antennas myself.
Well i have one or two which i would like some info on. So i will post them into the PHOTOS section and let you see the beasts. One i in need of repair which I hope some of you may be able to help me with some element sizes. Right i am just going to post them and return here to let you all know they are up....

4650. Re: Hello Everybody. I have some nice old antennas...!

Right ppl.

The 70cms Jay Beam works and have had some nice qsos on that to scotland from N yorkshire.

The 16ele Jay beam is in need of repair and I will need some help as to size for the reflectors and the element which is missing half way down the boom. The broken one is easy if I measure from the center to the tip and double.

The slot fed 8x8 yagi i have not used yet but somone told me its 14db.

Any info on these antennas would be great. They are in the photos under (M3XLG Antennas).

I also own
7ele ZL Special
12ele ZL Special
Double size G5RV
EVX6000
Comet GP15
Antron 99

Do I fit in on this site is the burning question?

The only ones i dont use portable are the G5RV , Antron , GP 15...

Yes I am crazy.....

4651. 2nd Tilt Up

Yahoo group: ham-antennas (2008)
Date: 2008-04-06 22:54:39 UTC
From: Rich Schmuke
Topic: 4651 Message: 4651

I just posted some pictures of another tilt set up. This one can be put close to you house and them braced at the roof line if needed. It extends only on one side , not two like my first tilt up pictures. Also it is adjustable so the mast is completely vertical. This one is a little lighter duty and will be used for a 20m vertical , it can also be used as a dipole support. It has just been installed and still need a paint job. I can provide drawings for either set up.

It's Spring. I have this urge to change my antenna system.

A section of my house is nearly square. And, it is about 35 x 35 x 35 x 35 feet. Maybe it is time for a loop on top of the house, giving it a height of about 24 feet.

What say you?

4654. Two antennas on one coax

Yahoo group: ham-antennas (2008)
Date: 2008-04-20 13:55:15 UTC
From: noswadplease
Topic: 4654 Message: 4654

Hello group, I have an Icom R75 and a Yaesu VR-5000. One of my antennas is an AOR SA-7000 about 40ft up. Since the Yaesu receives up to 2.6 ghz and the SA-7000 receives to 2ghz, I was thinking about adding a discone rated to 3ghz. What I am thinking about doing is connecting it to the same coax as the SA-7000. It would be about 50 ft away and connected by coax to a tee connector. Has anyone tried a similar scenario. I can't find too much info on the net. I am hoping that it is far enough apart not to cause problems. Any input would be appreciated. By the way this is for DX'ing only. Thanks Ed Dawson

Assuming you only want one active at a given frequency, using a T only works correctly if one antenna presents a very high impedance when the other antenna is resonate (low impedance). This forces the resonant antenna to be active at the desired frequency. Not knowing the impedance curves of the two antenna I can't say if your setup will meet that criteria.

Problem is, ,at UHF and above, every foot of coax,every little connection,bend, coupling,switch, etc. has a loss effect on the signal. I would not do it.

Anything is possible. A two meter mobile 1/4 wave on a tool box might be easier though. I see drilling out the middle of the dish, mounting a quarter wave 2 meter nmo mount antenna in the middle. Never have done this but seems easy enough.

I'm on the ground floor of a two story building. I tried making a 300 ohm twin lead j-pole. And then sticking on a wire tape, and pushing it up one of the vent pipes. But it didn't work too well, and it destroyed the twin lead. I have a aluminum j-pole, and I have it mounted on my grill. But I don't think my complex is going to like that idea too much.

That's simple then, use a plant and low power. If you can have plants mount it in a bushy plant. It won't work as well without a ground plane but it should work ok. Or get a flower pot, soil, aluminum foil (put holes in it for water drain) mag mount antenna and plant. Make a doughnut out of the foil about one inch down from top add plant and mag mount 1/4 wave and cover to the top. Currently I have a 1/4 wave in a bush with the wire going besides the cable tv wire into the house. It works for most of the local repeaters. 73

Did you leave it on the wire tape?? . A antenna made from twin lead needs a min of ¼ wave clear at the base. What are your walls made of? Today many are constructed with sheet metal studs for fire safety. Running an antenna through or close by the studs wont work. A twin lead antenna on a plastic stick in a flower pot should be OK , who can complain about a support for your plant that is going to grow a wave length high , I mean as high as the vine will be.

Yeah, I left it on the fish tape to give it something to hold the twin lead. I thought it was a great idea, but it failed to live up to what I had hoped. I am really considering getting a pre-made J-Pole. I really only use my radio for aprs.

4666. Suggestions for skyhooks to make an outdoor loop

Yahoo group: ham-antennas (2008)
Date: 2008-04-22 15:11:00 UTC
From: Hal Thomas
Topic: 4666 Message: 4666

With the limitations of the back yard I have I am looking for suggestions of what others may have used as skyhooks for hanging a Horiz loop. I am basically looking at a rectangle shape with vertical posts in 4 corners of the back yard. What have you used that gets a good height and is solid and doesn't make the neighbors think you have installed Missle Silos :) Thanks Hal

I haven't done it yet, but what I'm considering is to use hurricane fence top-rail. It's sold at Home Depot in 10' sections and is galvanized. I know for sure that two of them, with sheet metal screws run through at the slip joint are quite strong and won't need guying. I run this configuration for a dual-band vertical mast now.

What I don't know yet is how three sections would hold up to the stress of hanging a loop...but that is what I'm thinking about trying for the two back supports for a horizontal delta for 80m and up.

Hal , I have no problems with neighbors but I can not climb due to a bad back. I just installed a tilt-up post that would work in a corner, or 4 corners . Check out the pictures the photo site for here. This set is only 30 ft tall , I am going to mount a 20m vert on it.

The same base had a 40 ft set up on it before. I used parts from that 40 ft set up to make my other shown tilt up. The height is only limited by how much pipe you want to buy.

Hal,

I use a 20 foot varnished stair-case handrail in one corner and an old Windsurfer's Mast in another.

You say a square loop? My friend and I have been doing some modelling and if you can make an equilateral triangle, there does seem to be some excellent lobes of gain that appear to be better than square shapes.

Food for thought.

Callum McCormick
http://www.m0mcx.co.uk/

While others were busy thinking outside the box, I cut it up because I needed some cardboard for a project I was making.

The same base had a 40 ft set up on it before. I used parts from that 40 ft set up to make my other shown tilt up. The height is only limited by how much pipe you want to buy.

Subject: [ham-antennas] Suggestions for skyhooks to make an outdoor loop

With the limitations of the back yard I have I am looking for suggestions of what others may have used as skyhooks for hanging a Horiz loop. I am basically looking at a rectangle shape with vertical posts in 4 corners of the back yard. What have you used that gets a good height and is solid and doesn't make the neighbors think you have installed Missle Silos :) Thanks Hal

Yes there are 2 , first tilt , projects two ways as the pivot is at the top , tilt 2, the pivot is at the base , I can send you a drawing by direct email. If you have a spam filter add me so it will get through.

Rich,

It appears that there are 2 different ones pictured.

Can you provide more detail on the 1st picture

Thanks

Rich Schmuke <rdj@... <mailto:rdj%40wildblue.net> > wrote:
Hal , I have no problems with neighbors but I can not climb due to a bad back. I just installed a tilt-up post that would work in a corner, or 4 corners . Check out the pictures the photo site for here. This set is only 30 ft tall , I am going to mount a 20m vert on it.

The same base had a 40 ft set up on it before. I used parts from that 40 ft set up to make my other shown tilt up. The height is only limited by how much pipe you want to buy.

Forwarded Message:

It is with a heavy heart and infinite sadness I report the passing of LB Cebik, a friend to us all.

I had called the local Sheriff in Knoxville, TN to go check on him since I hadn't heard from him in over 5 days (either email or phone), which is highly unusual.

The Sheriff called back to tell me this sad, devastating news. He was like family to me and was loved and respected by so many. I remain in shock as I tell you this.

I need to locate his next of kin as he did not have family in Knoxville.

Happy Trails,
Jack L. Stone

This is a loss to Amateur Radio. I also had correspondence with him. He was very patient and instructive on any level . Too bad he had no local family. I hope he did not have a health crisis and there was no one around to help him !
Anyway, he was a Hams Ham! R.I.P !

All of Ham Radio morns the loss of such a great icon. I have read threw his web site extensively in the past researching antennas and it would be a great loss if it gets shut down I'm going to capture the site to my hard drive in case it gets shut down. If so I'll put it back up some where else I already manage several other sites.

Topic: 4679 Message: 4679

Hi,
I want to site a Hustler 6BTV at our holiday home as I spend most of the summer there. Unfortunately the developer doesn't allow any radio antennas on the holiday complex.

I was therefore wondering if it would be possible to place a 6BTV inside a totally enclosed soil pipe (5-6 inch dia' plastic pipe) and fix to the wall with radials buried in the garden?

Has anyone else tried this method? As I'd be interested in how it affect the antenna's performance.

Sorry so many questions I know.

HI Danny,
Can you tell me somthing, i have the HUSTLER 5BTV but i have those 6 x 12inchs mini radials near the top end of the ant.
but the 6BTV does not , i was wondering why???
have not erected my hustler yet, just got it second hand, and i find it very heavy. so will prob sell it.
like the look of that TAK-tenna. as i am in a very restricted area. live in a terraced house. with a small backyard. so i am only able to fit a 20m
Dipole from chimney to a pole at back entry wall.
thats why the TAK-tenna caught my eye.

some plastic absorbs RF and causes it to heat up.

Try putting some of the plastic in a microwave oven
and see if it heats. If not, then put the 6 BTV
inside the pipe and test for heating using your transmitter. If it
shows the slightest amount of temperature rise, (the plastic pipe)
then I don't think it's a good idea.

I just put up a 6BTV at my house two weeks ago. Like you, it is also an antenna restricted area. I have it ground mounted at the back of my yard (which boarders to a small grove of trees that are outside of my property lines). I used some Krylon flat black spray paint and found that it makes the antenna vertually disappear! The shiny aluminum tubes stood out and now that I painted it black, it blends in with the surrounding and is not as conspicuous.

Also, Google search for 'Flagpole Antenna'. There are many really good designs out there that work great. Good luck and good dx!

Cheers & 73

PVC, when burned, creates HCL, hydrochloric acid. Not all plastics do this, but PVC does.

Be careful.

Hello Members!

Like most of us, I am always on a tight budget, so I am always on the lookout for freebies, samples, cheap deals and bargains.
It does help!
I just joined another brilliant group for freebies, so I thought I'd share the info: http://groups.google.com/group/freebiefinder

Its an excellent group, and has lots of stuff which is completely free! I just downloaded some of their fantastic audio books, free!,and foundsome fantstic links to other free stuff.
Go and join, it costs nothing!

Oh..almost forgot!..I found some great freebies today that you can apply for:

5 free top selling books & a ton of other BIG offers!

Why not just put a 2x3 foot flag at the top,
and call it your flagpole. If someone says take
your flagpole down, I think that's illegal.

From: Ted Horishny
Topic: 4691 Message: 4691

Has anyone seen one of these? IV3SBE's website markets this along with construction info for the matching transformer. It looks like a fiber mast at least 32 feet long attached to a pvc extension about 4 feet long which has the transformer mounted to it. Bottom pvc piece seems to have a spiral winding. Anyone know? Thanks in advance.

Dan ,

I have made 2m Slim Jim and other types of antennas and installed them in PVC. I found that you need to adjust the tuning by about 19% , I don't know if HF would have the same affect as the higher frequency. Also you will find the Hustler heavier that the Cushcraft because made from heavier parts that will last longer in high wind loads. I would trade you my Cushcraft for you Hustler.

Hey, it ain't that simple.

I did that and I can't get in. (Yes, I requested the "Free Membership, received the verification email, and confirmed it.)

Not only that but there is no link provided for a webmaster, or anyone else to service login problems.

Attempting to register again resulted in an error message with instructions to "Visit the Control Panel to view your account." Um, what the heck is the Control Panel (other than the one on my PC)? There ain't no link for anything called a Control Panel.

I think someone hijacked Mr. Cebik's website and it's already gone.

What web browser / version are you using?

I'm starting to think it's something specific to a web browser that makes it work or not work. This computer runs Microsoft Internet Explorer version 6 and maybe that's the problem? Maybe the Antennex guys wrote code that only works with version 7, or Firefox or something.

You register, then get an email, you click to confirm and another email arrives with your password...and it isn't the password you set the first time. It took several minutes for that last email with the site generated password to arrive here.

The subject has "Your New Membership Account" in it.

I then clicked on that link, logged in and changed my password again.

Did you overlook that second email from the site with the generated password it sends?

4699. TGM COMM. MQ-26SR HYBRID QUAD mini beam

Yahoo group: ham-antennas (2008)
Date: 2008-04-25 03:27:35 UTC
From: wv2c
Topic: 4699 Message: 4699

Hi All ...new to the group...need your advice!
Have a space issue and considering only the MQ-26SR hybrid mini beam, the cushcraft MA5B and the Mosley MINI 33A WARC. All are around the same price. The MQ26SR boasts the best overall gain on all bands. I see ok reviews on the MA5B and almost nothing anywhere on the Mosley.
To be honest I am leaning towards the MQ-26SR. Does anyone have any experiences to offer?
Many thanks to all.

Topic: 4699 Message: 4700

Yes sir - I have an opinion anyway - Mosley will be there when the ice takes the others away and it will perform at least as well - I like the Cushcraft VHF antennas but the HF antennas are no ways near as heavily built as the Mosley. The gain figures are all set by the advertising department anyway, I doubt you will be able to tell the difference in signals between the three- (one more thing) on the Mosley,
if you operate 6 meters at all, check its operation on the bottom end of 6. I know they do not advertise it as such, but just check it and see what you find.
Worked for me. Dave / N?ATH 73 & Good Luck Tony

I have the same space problem and have been considering the same antennas and the Force 12 C3SS. One differentiator for me is that the TGM claims gain on the WARC bands.

I also think the MQ-26SR might be the "sweet spot" in their 6 band line.

I've traded sleep for reading that site many many times. I'm glad it will still stick around. It's a lifetime of knowledge.

Antennex have been on the prowl telling other sites they can no longer link to cebik.com though, I hope that doesn't foretell something bad happening. It's definitely not in the spirit of the author for sure.

I hate to think how many "I'm new to ham radio" emails that man answered over the years but I was stunned when he would reply to me any time I had a question about the material. That always amazed me.

From: NS5B@comcast.net
Topic: 4707 Message: 4707

Anyone have a spare Rohn TB-3 Thrust Bearing to sell? I have everything in place, but before I can install my antenna and mast, I require a thrust bearing. If I had a newer more robust rotor, I wouldn't worry about it, but due to the weight of the 20' mast, and the large 7 element tri-bander, I prefer to use a bearing to help support the load. This is the only thing that is holding me up.

Would be nice to buy from someone with a paypal account, but I can send a MO also.

Thanks,
Steve, NS5B

4711. Antenna & the Coax Connection Question

Yahoo group: ham-antennas (2008)
Date: 2008-04-25 19:13:29 UTC
From: foreveraccount
Topic: 4711 Message: 4711

If you connect the center conductor of the coax to the antenna, and remove the surrounding shield and go to radials & ground with it, won't water get in the coax now since there is an opening in the coax on the end??

Hi everyone,

No need to worry, www.cebik.com is online and running,
thanks to Jack Stone of Antennex. Jack was publisher for
LB Ceibk, sponsored www.cebik.com as well as a good friend.

The delays could be from everyone obtaining the secure login.
This keeps out the bandwith hogs that link to your site and
use up all your bandwidth, along with attempting to download
the entire website for their own use.

any questions, visit www.antennex.com

Yup ,and 9913 is the worst kind to do that. Most of the time they forget to tell a person to seal the end of the coax. You can use a little RTV and/or epoxy. I use epoxy for fast drying and it seems to hold up a little better, I also use shrink on the coax fittings if I use UHF , type N is better. I also use clear finger nail polish to seal the ends of the shrink if I am working with 9913 or a poly foam type , the solid is more water resistant . If you use a center support for the dipole that you can wrap the coax around and then point the open end of the coax down, that is better.

Is that a help???

If you connect the center conductor of the coax to the antenna, and remove the surrounding shield and go to radials & ground with it, won't water get in the coax now since there is an opening in the coax on the end??

Awesome. Tried it again, and it worked great this time. Was able to sign up, and received the verification seconds after entering my information. Clicking on the link conformed my info, and again, only seconds until I got a my login password. Thanks Jack! and all involved.

Hi everyone,

No need to worry, www.cebik.com is online and running,
thanks to Jack Stone of Antennex. Jack was publisher for
LB Ceibk, sponsored www.cebik.com as well as a good friend.

The delays could be from everyone obtaining the secure login.
This keeps out the bandwith hogs that link to your site and
use up all your bandwidth, along with attempting to download
the entire website for their own use.

any questions, visit www.antennex.com

Hello, I've ran the TGM 20-6 meter hybrid quad for several years. For the most part I've been pleased with it. It does have gain, light and small wind load, only needs a light duty rotor. On the negative side, narrow bandwidth. It has survived the winds of western montana, so its pretty hardy. I'm in the process of replacing it with a broadband hexbeam (homemade). If you go with the TGM I think you'll be happy with it, I know I was but now I want something with more gain...73, Alan

Hi,
I'm new to the group. I wanted to either make or purchase a field antenna for HF. It has to be lightweight, easy to put up, and have multiple bands w/o having to move clips on tuning coils. I would like to have 80m, 40m & 20m at a minimum. And the last part is to have as small a foot print as possible. I like the buddie pole but I don't like the idea of having to move clips around when you change bands. Any suggestions from the group?

I built a portable antenna once using a 3lb coffiee can in the bottom of the can I installed a 3/8 antenna mount that I would screw a 102' steel CB whip into inside the can I put a coil that I had taped for the different bands and then installed a waffer switch to switch from band to band I used it with my HW-8 when I went camping. Just one idea.

Yes, it will get water in it when it rains.
And it is amazing how many hames with advanced or extra class licenses will and have done exactly that kind of thing.
It is possible to seal it, but with care as to what kind of sealant is used.
I always tape the connectors I have up outside, been doing it since the early 70's when I used to install TV antennas...
Properly taped, a connection will stay reasonably good through the years.
YMMV

After I tape a connection, I wrap it with rubber mastic tape, then I apply several coats of liquid tape. That stuff is fantastic. Makes for a moisture proof connection. Be aware though, my method can be a real challenge when trying to get at the connection later when changing antennas etc.

Would a horizontal dipole work? With a launcher like the EZ-Hang you can string a dipole easily in trees. A fan dipole or a parallel dipole would be multi-band, or you could use a tuner on a simple 80M dipole and get all you want.

BTW- though the EZ-Hang is around $100, you can make one for about $25 from Wal-Mart parts. That's if your state allows the sale of slingshots. I built one and I love it.

Thanks for the feedback, I'm thinking the internal antenna tunner on
the 746 Pro will help me out especially on 20 meters. I will be
replacing a Cushcraft R6000 vertical .....Tony

4725. Wire radials v chicken wire

Yahoo group: ham-antennas (2008)
Date: 2008-04-26 13:49:00 UTC
From: Donal
Topic: 4725 Message: 4725

Hi,
I was wondering which would be best as a radial system for my 6BTV, some copper wire or chicken wire?

I was also planning on peeling the grass and about 2 inches of soil back to bury either or both... would this be okay or should it be tacked down on top of the grass?

The other thing is I have about 100m of copper wire donated to me for antenna projects, problem is it is insulated... so I was wondering if I need to burn the insulation (plastic) off before using as radials if I choose the copper wire over the chicken wire.

Much thanks for reading.

Sorry Email hiccupped and sent before I was ready. You don't want to use chickenwire as the really good stuff will cost a heck of a lot more and not last as long as copper. My chicken coop needs major repairs after 5 years to the pen area and most of the problem is rust.

I use 48 copper wires cut for several bands. I have stripped the wire and not stripped the wire, difference about .1 to the velocity factor even in a fat and parrel dipole and Radials. My advice don't sweat the small stuff your local interactions will have a greater effect than the insulation.

I would use an all band doublet style antenna cheap, easy to set up and effective. The EZ-Hang that I made cost me about 18 dollars. 2 for a bag of sinkers, 7 for the slingshot, 7 for the Zebco 202 (I should have spent a couple more for the 404) and the rest for a piece of 1 inch dowling, a broom handle will work as well, the rest for a 3 inch bolt, a nut and two washers to hold the reel out front. Works great and I can hang stuff up to about 60 feet with it. Beyond that I use my compound bow, a blunt arrow, glued a spent cartridge up front with hot glue and the same reel. A fix the reel to the dowl with electrical tape and a couple of wire ties.

Good Luck and good DX

I imagine the radials's capacitance to the ground is the thing, which is
there even with the insulation on. A direct DC ground is necessary for
static lightning protection IMHO.

Yes and you can tie the radials to the dc ground (not a bad idea) the radials couple via capacitance and the DC is a straight ground. I tie all to a central DC ground switch, and use large dia wire #6 to the ground rods I use 3 joined by a piece of strapping made from a piece of fridge water coil that I bought at the home store. My last ground rod has 4 #6 wires running out an extra 20 feet about 6 inches under ground near the drainfield. All antennas towers etc are tied to this system. My Granddad was a ground electrian in a powder plant. he taught me what a good DC static ground takes.

Ensuring that there is as little trapped air underneath whatever type sealant you use, tape the outside too with at least two layers. The last layer not pulled very tight so you won't allow the wind to pull it off. Quality tape (thicker the better) works much better and doesn't "flag" off" as much as the cheap/thin stuff.

Subject: [ham-antennas] Rohn TB-3 Thrust Bearing

Anyone have a spare Rohn TB-3 Thrust Bearing to sell? I have everything in place, but before I can install my antenna and mast, I require a thrust bearing. If I had a newer more robust rotor, I wouldn't worry about it, but due to the weight of the 20' mast, and the large 7 element tri-bander, I prefer to use a bearing to help support the load. This is the only thing that is holding me up.

Would be nice to buy from someone with a paypal account, but I can send a MO also.

Thanks,
Steve, NS5B

Forget the chicken wire. In a year or two at the most it will be all gone. And don't worry about the insulation on the wire. It does not make any difference. Put down as many and as much as you can and in any direction possible. A perfect spoked wheel would be ideal, but you will not be able to tell any difference if yours is not perfect. With buried (or on-ground) radials the rule is "More is Better".

Hi,
I was wondering which would be best as a radial system for my 6BTV, some copper wire or chicken wire?

I was also planning on peeling the grass and about 2 inches of soil back to bury either or both... would this be okay or should it be tacked down on top of the grass?

The other thing is I have about 100m of copper wire donated to me for antenna projects, problem is it is insulated... so I was wondering if I need to burn the insulation (plastic) off before using as radials if I choose the copper wire over the chicken wire.

Much thanks for reading.

4738. Grid -vs- radials

Yahoo group: ham-antennas (2008)
Date: 2008-04-27 20:17:03 UTC
From: Callum M0MCX
Topic: 4725 Message: 4738

Following on from the chicken wire -vs- radials discussion, does anyone have an opinion if a grid system is any different (in practice) to a radial system since It will be easier for me to put a 2 foot grid down than a 120 radials system in place for a 40m vertical.

Ground area is about 45 feet by 30 feet.

Regards,

Callum McCormick

From: Callum M0MCX
Topic: 4699 Message: 4739

I have had an MQ (20, 15, 10) and a number of friends have them too. One fella around here has the 6 band: 20, 17, 15, 12, 10, 6. Works great. 20m is less directional because of the compromise but in the event you are in mini-beam territory anyway, you won't be far off.

Oh.. advice and after sales direct from Tom at the MQ factory is second to none too.

Cheers,

Callum McCormick

Tony

I have the same space problem and have been considering the same antennas and the Force 12 C3SS. One differentiator for me is that the TGM claims gain on the WARC bands.

I also think the MQ-26SR might be the "sweet spot" in their 6 band line.

4740. Re: [ham-antennas] Grid -vs- radials

Yahoo group: ham-antennas (2008)
Date: 2008-04-27 21:14:22 UTC
From: W5CPT
Topic: 4725 Message: 4740

Think of it this way. The "Absolute Ideal" would be a solid circular plate of metal at the base of the vertical with a radius being a quarter wave at the lowest frequency at which the antenna is designed to work. Please notice I did not say anything about the physical height of the vertical radiator as the actual length and the electrical length can be very different (loading etc).

***** Any thing you do that is less than that is less than the "Absolute Ideal". *****

With that being said, we will now look at the "Practical Ideal". This will be anything that approaches the "Absolute Ideal" in both physical and electrical characteristics. The farther you get from the "Absolute Ideal" the less like the "Absolute Ideal" it will be. Many many many antennas have signal ground systems that are NO WHERE NEAR the "AI" and still work very well, but the fact remains the closer you are to the "AI" the better it will work.

At some point in putting down the radials, ground screen, Spider Web ground system or what ever you have chosen, you will reach a point of Diminishing Returns. That is the point at which you can no longer hear or see or measure the improvement to the electrical performance of the antenna.

I have read that with 1/4 wave radials (depending on your soil conditions) that point is about 30 something elements. Many (this includes me) think that 48 is the optimum number from a practical and electrical perspective.

Bottom line on ground mounted or shallow buried ground systems is:

Put in as many as possible as long as possible and don't worry if 2 more (either radials or square feet of screen) would have made a difference because if it did, you most likely couldn't tell the difference.

"my opinion and worth what you paid for it"

4741. 6 BTV Rooftop mount - Opinions?

Yahoo group: ham-antennas (2008)
Date: 2008-04-27 23:35:23 UTC
From: Ruben
Topic: 4741 Message: 4741

I am considering installing a 6BTV antenna on my rooftop, how many radials do I have to install? What should I expect as far as performance. Right now I have an Alpha Delta DX-CC on the roof but since the space is limited it's setup like a horizontal Vee at about 10 feet at the apex. The tips are about 30 feet apart. Needless to say I am causing lots of TVI in the building (3 story 6 family).
Also not getting good performance, although been very active on PSK but I feel that it could be better. Any opinions? I'm shooting for the beginning of May for the installation...
TNX in advance .. Ruben KA2HHB

4742. Re: [ham-antennas] 6 BTV Rooftop mount - Opinions?

Yahoo group: ham-antennas (2008)

Ruben:
The 6btv will be a great antenna for you. Just like all non-ground mounted verticals it will require radials, as usual the more the better. Hustler will tell you that you "really" don't need them. A 6btv MUST be guyed if mounted on the roof. (the 30 meter trap makes it very top heavy) I use a small nylon rope. (which should affect the performace, but has not that I know of) when it gets wet. Hustler will also tell you that the antenna is intended to be "free space" i.e. not grounded. They say the 80 meter resonator will handle the strike.....be your own judge on that matter...

Hi,
The small diameter Kevlar cord,sold by Radio Works,works good
for guying my ground mounted 4btv and Hustler HF2V.Does'nt absorb
water and seems to last a long time.The nylon cord,will stretch a
good bit when wet and if there are nearby obstructions around,may
snag and cause the antenna to bend.

4744. Cubical quad - height above real ground?

Yahoo group: ham-antennas (2008)
Date: 2008-04-28 16:48:23 UTC
From: vaclav_sal
Topic: 4744 Message: 4744

Vertical "take-off" angle of a dipole depends on the height above real ground.
Same applies to other antennas including cubical quad.
My question is - in quad - where is this height above ground measured from?
Is it from the lowest point of the antenna or from the center of the antenna?
For example - diamond shape quad has definitely lower point adjacent to ground than square shape. However, the center of both shapes is in same distance from the ground.

It probably does not matter that much anyway, but like to know the real scoop.

Second question ☐ very theoretical ☐ are there any programs / graphs illustrating propagation distances depending on the "take-off" angle?
I was thinking a single skip with fixed ionosphere reflection point height versus take-off angle.
Of course only in pure mathematical theory.
Thanks for reading,
73 Vaclav AA7EJ

Hi All,

Early this summer, I plan to erect a mast on a side peak of my home and on that mast mount 2 antennae. I will use a Scantenna for my Uniden BCD996T scanner and I'll also mount a VHF stick w/ counterpoise for VHF/UHF (140/220/440). Since I'll frequently use both radios simultaneously, how can I mount the antennae in such a way as to not overload the scantenna when I tx on VHF/UHF?

As a secondary question, re lightning protection - can I simply sink a ground rod and run a ground wire up and termiante it on the mast?

Thanks in advance - sorry if these questions have been asked before.

From: James Fogg
Topic: 4745 Message: 4746

For most mast-mount transmitting antennas, the least amount of energy is radiated underneath the antenna, below the ground plane. Place your Scantenna below your other antenna. It is unlikely you'll avoid at least desensing your Uniden receiver, but at least you shouldn't damage it. You may find that it gets so overloaded that it stops scanning and may actually demodulate your signal.

For lightning protection most modern antennas should be grounded as you describe, assuming everything is metal and there's no paint between the antenna mount and the mast. Lightning protection actually is more about draining static charges rather than directing a bolt of lighting into the ground. It may have to do that too, but it might only do it once ;-) An additional transmission line (coax) lightning arrestor is a very good idea. Your ground rod should be deep enough to always be in contact with wet soil, even during dry spells. In much of the country this means 10 feet down.

As far as grounding, it is recommended you ground the antenna mast to your house electrical service ground. Where the power from the pole enters the house at the meter there should be a good ground stake. That's where cable grounds,too. Keeps everything at same potential.

Subject: Re: [ham-antennas] 6 BTV Rooftop mount - Opinions?

Ruben:
The 6btv will be a great antenna for you. Just like all non-ground mounted verticals it will require radials, as usual the more the better. Hustler will tell you that you "really" don't need them. A 6btv MUST be guyed if mounted on the roof. (the 30 meter trap makes it very top heavy) I use a small nylon rope. (which should affect the performace, but has not that I know of) when it gets wet. Hustler will also tell you that the antenna is intended to be "free space" i.e. not grounded. They say the 80 meter resonator will handle the strike.....be your own judge on that matter...

Thanks, Phil. That makes sense. I hadn't thought of that.

Now I just need to figure out the antenna setup.

If you can find it...

There was an article in the May 1999 issue of "Electronic Design" complete with a picture of the world's largest ground plane...

It measures 50 X 80 Meters... and is a solid copper plate ! ! !

See :
http://findarticles.com/p/articles/mi_hb3021/is_199905/ai_n15197519

4754. M3KXZ 2 Element Vertical Phased Array

Yahoo group: ham-antennas (2008)
Date: 2008-05-02 01:12:25 UTC
From: Bruce Conner
Topic: 4754 Message: 4754

I was wondering if anyone had any observations about this antenna.
(see http://www.outsideshack.com/no_counterpoise_phased_array.pdf)

The late L.B Cebik did a review of it and seemed to think it had some real promise, but he indicated that feeding the antenna might be done better. I have the rather sad distinction of having emailed him about this on or about the very day he left this earth. I was really looking forward to hearing his views and getting to know him. I'd been too intimidated to approach him before! Lesson learned; don't wait to ask the guru, they may not be around later. If anybody else wants to be an Antenna Elmer, let me know.

In any event, I'm interested in this antenna for 10-20 meter work, and would rather feed it with 450 window line than coax, since I don't have a remote tuner. The window line would come back into the shack to my Harvey Wells balanced tuner that I normally use for my ladder-line fed horizontal 80 meter delta loop.

One main objective is to keep RF out of the shack, so I'm wondering if a 1:1 transformer at the center feed where the phase crossover happens would be good for a window line feed, replacing the suggested 4:1 balun that was used to match the coax. Cebik didn't seem to think even the 4:1 balun at the feedpoint was quite the right thing in his review at:
http://www.cebik.com/content/a10/wire/m3kxz.html
(you'll have to sign in now, but it's still free - well worth it)

I have the makings for this antenna on hand, aside from the remote tuner, so any suggestions will be welcome. Would using "real" twinlead rather than speaker cord be an improvement? Will it perform "as advertised?" What about a 3 element version to get a front/back ratio going? All sorts of questions pop up if this turns out to be a decent design.

I'm anxious to try it and see what a directional antenna with a lower takeoff angle can do for me. I'm constrained in that it has to be able to be dismantled and stored between uses. I see this as a "weekend contest" or even Field Day type antenna, not a daily driver, due to neighborhood aesthetic concerns. (my loop is in the back, but this would be more visible)

73,
Bruce

Bruce,
I did take a quick look at the article.
Sounds interesting, however, I would not call it Zepp.
I thing "folded Windom" may be better, but it really does not matter what you call it.
I will take a peek at the modeling and let you know later.
Personally I think the balluns are OK but it may work better without them.
I have recently experimented with 20 meters double extended Zepp - inverted V style and jury is still out pending better propagation on 20 meters Hi Hi.
I did use 9:1 ballun at the feed point and cheap RG 58 to shack.
I could match it on 20, 40, and 80 but made contact only on 20.

4756. Importance of beam element straightness

Yahoo group: ham-antennas (2008)
Date: 2008-05-02 15:04:38 UTC
From: Kenny Wyss
Topic: 4756 Message: 4756

I just about have my tower project complete and will hopefully be raising antennas up over the weekend. I have made some repairs to my HF beam and cleaned the whole thing up with some steel wool. It is a Hy-Gain TH3-MK3 10/15/20 meter beam. I have noticed that, due to the antenna's age, the elements do tend to sag slightly and don't have a perfect horizontal plane. Does anyone have any idea how much this may effect the performance of the antenna? I would say that if you measured it, the very end of each element sags about 8 inches lower than where the other end attaches to the boom.

Thanks and 73,

Kenny

Hi Joe,

I just saw your reply - sorry about that. My thought process was such that because I read rave reviews on the scantenna (how it blew away everything else), and because I live in a low-lying area, that I should go in the direction I had described. But I am open to alternative ideas. I will check out the Diamond.
Thanks very much for your suggestion!

4760. Best Gain Vertical for 2meters

Yahoo group: ham-antennas (2008)
Date: 2008-05-03 09:00:23 UTC
From: Chris Moore
Topic: 4760 Message: 4760

Right ppl. I am in the market for a new antenna. I have since found out that No beam works in my location due to all the hills and I mean they dont work at all. The vertical works best as it picks up all the bounced signals being that its a Omni.

I have been looking at the Diamond X510 and LamCommunications LAMCO CGF 6000 'High Gain' VHF/UHF http://www.lamcommunications.net/sess/utn;jsessionid=15481c28e7eafe3/shopdata/index.shopscript has anybody got any other ideas. I dont want to go silly on price as it may be blow down in 8 months with the high winds so its got to be a price I can afford if broken once a year.....hi hi...

Right fight amongst your selfs what you think and where to buy be nice...

I have an X510 now, it works very well for me. However, you said you had large hills very close in and the 510 by design has a very narrow and low takeoff angle. It's made to reach to the horizons. This could be an issue for you as well, just so you know.

Most high gain collinears have a similar pattern due to their properties. They get the gain by narrowing the pattern and 'focusing' the signal if you will. If this narrow band hits the hills, you aren't gaining anything.

As far as heavy duty, NJ winds aren't very high so it's fine here, barely moves in big storms using hurricane fence top-rail sections as masting. If you want a heavier version, one that is substantially heavier fiberglass, get the X500HNA variant. It's quite a bit more heavy duty construction.

There are people who, due to terrain limitations get better performance from an X50 with its broader angle of takeoff, than they did with an X510 high gain design.

I'm sort of curious...what types of beams did you try? How many elements, boom length etc?

An NVIS dipole might help get you out of your valley. They only work well, though, for 160, 80, and 40 meters. About 20 or 25 feet high would do it.

4765. Re: [ham-antennas] Best Gain Vertical for 2meters

Yahoo group: ham-antennas (2008)
Date: 2008-05-03 13:56:50 UTC
From: NS5B@comcast.net
Topic: 4760 Message: 4765

I use the X50 myself, and due to the proximity of the repeaters around me, thats all I need, and its mounted on a "side mount" on my tower, so the height was an issue as well. Tower is only 40ft and the X50 is 5.5 feet tall. (pretty good gain for a short antenna) And mounted at 30ft gives me plenty of room below where my beam will mount. Since my tower is freestanding, I didn't want any extra load on top. We have severe storms through here all the time and high winds at times too. It works real well for me...get about 4.5db gain in 2 meters, 7db on 70cm, and with my 5 watt HT, I can hit just about any repeater in my area. If I had the room, I would have purchased the X510 myself. Its a great antenna, and has almost double the gain as the X50.

If I ever get a 100ft+ guyed tower, I will put up my 15el Cushcraft "Boomer". But for now, a vertical fits my needs.

In your case, I agree, I would go with a little bit wider takeoff...may have to forfeit a little bit of gain, but it should work out well. I've never used a LAMCO antenna, so I can't comment on that one, but it looks impressive at 5.6m tall and 9db gain. The winds and storms here would snap that thing right off though.

Steve, NS5B

I would make a ¼ wave with a few pieces of 12ga wire and an SO239 connector. It'll cost you about $2.00 and will have a "doughnut" pattern that will do what you need. Gain antennas almost always have complicated radiation patterns and nulls. You can always add power to make up for gain. Also remember that at 145Mhz the loss in your coax isn't small. Use good coax.

Right ppl. I am in the market for a new antenna. I have since found out that No beam works in my location due to all the hills and I mean they dont work at all. The vertical works best as it picks up all the bounced signals being that its a Omni.

I have been looking at the Diamond X510 and LamCommunications LAMCO CGF 6000 'High Gain' VHF/UHF http://www.lamcommunications.net/sess/utn;jsessionid=15481c28e7eafe3/sho <http://www.lamcommunications.net/sess/utn;jsessionid=15481c28e7eafe3/sho> pdata/index.shopscript has anybody got any other ideas. I dont want to go silly on price as it may be blow down in 8 months with the high winds so its got to be a price I can afford if broken once a year.....hi hi...

Right fight amongst your selfs what you think and where to buy be nice...

James, I love your practicality (!) but in my experience, modern gain verticals are clean as regards the far-fields plots they produce. I currently have the Diamond V2000 (2 x 5/8th on 2m) which is a superb performer and only about 9 feet long □ it□s basically the X510□s little brother.

(Not sure if you can get the Diamond brand in the US..?)

Cheers,

Callum McCormick

If you can find it...

There was an article in the May 1999 issue of "Electronic Design" complete with a picture of the world's largest ground plane...

It measures 50 X 80 Meters... and is a solid copper plate ! ! !

See :
http://findarticles.com/p/articles/mi_hb3021/is_199905/ai_n15197519

The Discone antenna is a utility antenna, no gain at all. In fact, performance is what i would call fair on 2 meter and up, but poor on 6 meters, and receive would be poor on frequencies below 50 MHz.
Quoting the hype on the discone "The discone design offers the best performance possible in an omni-directional antenna.", they should have mentioned that for a works on all bands above 2 meters, it is a fair antenna. Not great, just fair.
I have the version that Radio Shack sold, and it was fair on the 1 1/4 meter band, and did work on 2 meters and 70 centimeters.
On 6 meters, it was poor, and I redid it using a 6 meter hamstick in place of the whip and loading coil they provided.
I took it down when I built a J Pole for the 1 1/4 meter band. May put it up for scanner use, as well as for a utility antenna where a zilch gain antenna is okay.
Most antennas that cover more than one band tend to be a compromise, or be very large. Plus usually require a tuner, or are very narrowbanded on the frequencies they do work on.
YMMV

I currently have a Cushcraft A4 with the 40M option. It also has 10M, 15M, and 20M. It is currently tuned for the middle of the phone bands on each of the frequencies. Does anyone know if the antenna can be tuned for 17M without effecting the 40M band? I am not concerned about the other bands, only the 40M.

Vaclav,

Thanks, I'll be looking forward to your comments. The antenna is a
strange mix of styles, but according to Cebik's analysis it has some
unique qualities, especially being broadband, which is very useful for me.

I know what you mean about 20 meters these days! More sunspots soon,
and then we will all complain about how crowded the bands are.

I agree with your experience here. They are a compromise antenna.

I already have a Comet GP15 up on the house which is 6.2 db on 144mhz and it has got very low loss coax on it (ECOFLEX 15) 10meters that is so my losses are very small. Also over here I am a M3 licence which means I am only permitted to us 10watts MAX.....So i need the gain... Cheers for info. Anybody using RG213 get some proper Coax it DOES make a huge difference.....

I use a 40 watt iron , if out side and windy I use a 60.The 60 is almost too big to work with PL259's. I don't know how a larger iron would work for soldering the shield to the PL259. I also use a small bottle of brush on rosin flux and always Kessler lead based solder.

Long ago I briefly had a job as a production solderer/assembler. I had already honed my soldering technique from 10 years of childhood electronics projects. My style is based on speed to avoid heating the device you are soldering, since heat transfer is based on time and temp. I always use a very hot iron and work very fast and I have great results. The engineers at that assembly job had other ideas and management wanted a cooler iron to avoid component damage. I was able to demonstrate otherwise and taught a few of the women on the line how to work hot/fast and the failures dropped significantly.

What does my heresy have to do with coax? For the braid I use a micro torch (like Radio Shack carried years ago). For the center conductor I use a 60 watt (or larger if I have one). From my plumbing skills I picked up the trick of cooling the connector just to the point below boiling water with a wet rag as soon as I remove the torch. Speed is my key to success with solder.

For the most recent PL-259 that I soldered on LMR-400 I used a micro-torch made by the Blazer company. Very fast with no excessive heat to the connector or coax. I'm sold on that method. This little torch is small - abt the size of your thumb.

Thanks Everyone.

Looks like the answer is, it depends on your technique.
Either will do.

Thanks Again,

Dan

You are right, it is what you are comfortable with. I learned to solder back in 1974 doing wire bundles for navy trainers. Back then it was all wires soldering into the cannon plugs , We did not have the crimp type back then on the trainers so I learned with a small but hot iron.

Yeh top stuff the Ecoflex. I only fun the ECO10 because I only have a small run and thats up the old chimney on the house 10meters. It is very flexy and cuts out alot of noise also signals are alot stronger. I was 5/7 to a mate when i lashed it with ecoflex from RG213 I went up to 5/9 so its made a huge difference. Over here in the UK you can buy it here http://www.diodecomms.co.uk he imports it from Germany I think. Doing a contest tonight at 8 till 10.30 with ecoflex on my skeleton slot yagi on the top of the landy less losses on 144mhz.....

I used to use one or two Weller guns.
Biggest problems I had with those was my brother never kept them tinned
when he used them.
I still have several of them, mostly working, and one Rat Shack gun that
is terrible compared to the Weller's
For small stuff, I use and older Weller temperature controlled iron.
Should get a new tip for it, as the end does not want to stay tinned any
more. But it is too light for the PL259s.
It does depend in part on how you do it. I usually tried to tin the braid
a bit, and the end of the center conductor, before I assembled the cable.

Wayne WA2YNE who started with a 100 watt iron way back.

Just like any hamstick. Using the semi as a ground plain. Current I have the dual antenna (whipping in the wind) sorry, the center wire goes to the center of both antennas, the outer braided wire goes to the aluminum mirror mount. Now with plastic mirror mount becoming more common some times the outer wire isn't connected. With either setup 4 watts legal and a 1.5:1 swr 5-7 miles is common. Anything works if the swr is resonable. Another way to think of it is a random wire antenna. Hope that helps. 73

I think you are referring to the white fiberglass poles about 18 feet long,that you see in marine use, or base stations with no ground plane radials. One such model I've used is the "Antron 99". I cut/pasted a short explanation I found at:
http://www.firecommunications.com/debunk.txt

The Antron 99 is not a half wave antenna!
(Another myth destroyed)

You saw it, you looked at it, it was about 18 feet long, and right off the bat you decided, "It's a half wave antenna".....Well, you're wrong again!

The Antron 99 is a loaded 1/2 wave over a loaded 1/4 wave, variable mutual transductance tuned vertical antenna! "Anyone who had read the advertising would know this"! here is a link to the equivalent electrical schematic representation of the A99.

http://www.firecommunications.com/images/a99schem.gif
how anyone can look at this and call it a shunt-fed 1/2 wave defies reason.

here are the patent files for the A99
http://www.firecommunications.com/patents/antron99/

The term colinear simply means "in a straight line". Any antenna using 2 or more discrete elements stacked one above the other, is a colinear array. To be exact, it is a 2 element stacked colinear array for the 10 and 11 meter bands! Put it together and place the feedpoint at 37 feet above the ground, (which is approximately one wavelength at 27 mhz) and don't forget to connect the other end of the feed to the "base". Pick up the ground plane kit for it later on as this is a worthwhile addition! Besides decoupling the antenna from the feedline and optimizing the input impedance the ground plane kit will also help further reduce rf interference and TVI in the near field of the antenna.

Hope this helps,
Phil B

4793. Testing of a W2DU 4:1 Balun

Yahoo group: ham-antennas (2008)
Date: 2008-05-07 01:18:36 UTC
From: Marty Bluhm
Topic: 4793 Message: 4793

I'm getting ready to put up a 20m delta loop and in the plans, the author utilized a 4:1 W2DU balun for matching vice the 72 ohm matching section.

I've carried around a w2du 4:1 balun for years, never knowing when I would need it. I checked it out today and one of the inside wires was broken. A little solder and it is ready to be tested. Now the problem, I cant find any documentation on how to check it out and make sure that it is ok. Anybody had any experience with this type of checking out.

Thanks

James, I have used your fast and hot method for over 30 years,at my past consumer electronics service and now as a school board service tech. I often have to reflow solder on a hundred or more pins on a switch assembly in intercoms now,and I use a hot iron (pyro-pen in the field) and move quickly from one to the next. The solder flows smoothly and shiny joints result. I defend this method to the death. I've tried the low iron longer method, but it just heats up the work. Glad there's another cry of truth from the darkness!
Best,

Hi Marty,
If you have access to an antenna analyzer,make a 200 ohm load,
with some resistors.Place them across the output and connect the
analyzer to the 50 ohm side.Should show a 1:1 match(or close).It may
vary a bit,from fiteen to ten meters,but should be fairly close.

From: Wayne
Topic: 4790 Message: 4797

try reading his query again. He said "at home", not mobile.

To answer, I took a junk one apart, which was in terrible shape due to
the fiberglas deteriorating.
It has a matching coil of sorts in the base.
May be similar in a way to the basic Ringo type antenna, also 1/2 wave,
that uses a loop that is tapped to match the antenna. Same basic idea I
would presume, only more compact.
Some hams have used them on 10 meters by trimming the top a bit.
being as feeding a 1/2 wave at the base would not work due to the
impedence being far different, the matching coil takes care of that so the
impedence seen is about 50 ohms.
Should be something in one of the antenna books, or maybe to be found
online.

I have an old CB base antenna here, all aluminum, that I plan to see if I
can get it to work for 10 or even 12 meters. It, however, used radials of
sorts at the base, now gone other than stbs and one slightly longer chunk,
plus a matching transformer in the base.
Some were 1/2 wave, some, If I recall right, were 5/8 or 3/4 wave long.
I might be able to make wire radials for it, just need another good place
to mount it.
Beware old fiberglas antennas, they slowly discintegrate...
YMMV

4798. Good Ideas for using 450 ohm ladder line?

Yahoo group: ham-antennas (2008)
Date: 2008-05-07 14:41:32 UTC
From: staub_r
Topic: 4798 Message: 4798

I have a couple antennas which use 450 Ohm ladder line. Does anyone have a good suggestion on using this line? I know you are supposed to keep it 2 feet away from anything metal of any size. This makes it extremely difficult to mount on a roof where it must come close to rain gutters and such things. Also this feed line tends to catch lots of wind. Any suggestions on how to keep it from distroying it's self in the wind?

My point was NO verticle REQUIRES a ground plane or counterpoise. Without one though makes it inefficient.

4800. RE: [ham-antennas] Half wave CB style verticals

Yahoo group: ham-antennas (2008)
Date: 2008-05-07 21:18:56 UTC
From: Callum M0MCX
Topic: 4790 Message: 4800

Thank you for the responses - although completely inconclusive. I had a half-wave vertical with no ground on 11m before I was a ham. I compared this to an 11 meter 3-ele yagi that I built and the yagi normally (but not always) beat the vertical. I know it's quite normal to say "verticals without grounds don't work" however there's plenty of 2, and 70cms antennas without a ground that work very well. So careful thought is required here before shouting from the rooftops.

I need to know if a) someone knows on this forum the precise matching circuit of these very cheap aluminium half-waves and b) what ground-wave experiments have taken place with them. Clearly there's a bit of a knowledge black hole here. I have a suspicion that these half-waves (driven more than a wavelength above ground) might work better than anticipated.

Cheers,

Callum McCormick

http://www.m0mcx.co.uk/

While others were busy thinking outside the box, I cut it up because I needed some cardboard for a project I was making.

I am confused as to how those half-wave antennas (that the CBers often use at home) work.

Many of them are half wave and have no ground plane. I just can't work out how they are fed?

Anyone..?

Yeh top stuff the Ecoflex. I only fun the ECO10 because I only have a small run and thats up the old chimney on the house 10meters. It is very flexy and cuts out alot of noise also signals are alot stronger. I was 5/7 to a mate when i lashed it with ecoflex from RG213 I went up to 5/9 so its made a huge difference. Over here in the UK you can buy it here http://www.diodecomms.co.uk he imports it from Germany I think. Doing a contest tonight at 8 till 10.30 with ecoflex on my skeleton slot yagi on the top of the landy less losses on 144mhz.....

I've tried all the commercial portable antennas, and find the tuning process on all of them fussy. I like to change bands without rebuilding the antenna.

So I've gravitated toward a version of the Norcal Doublet (Google it). What I did was take a 50 foot length of speaker wire, tie a knot in it 22 feet down, and seperate the wires so that you have 2 22-foot legs. The remaining wire is your feed line. I tune this with a small QRP tuner, but you could use any type of tuner. This takes me maybe a minute to change bands.

I use a long "fishing pole" as a mast and can hang thhis as an inverted V... or I can tie a line to a rock and throw the rock over a tree branch and operate without the pole.

My signal is at least as strong as on the various commercial antennas. In fact, to expand the thought, my wire antennas nearly always outperform aluminum. The best I've ever used in the Buckmaster (see E-ham reviews)

4803. Re: Half wave CB style verticals

Yahoo group: ham-antennas (2008)
Date: 2008-05-08 12:32:32 UTC
From: Ian Miller
Topic: 4790 Message: 4803

As a young teenager without much money, we used to play with some cheapy antenna designs on 11 meters. The fiberglass vertical was called the Big Stick from Shakespear. What was this? We took a guess at a vertically polarized dipole, center fed. Nothing more than that.

So, we got some white PVC pipe and some aluminum rod, and built these vertical dipoles cut to 11 meters. They certainly out-performed the 1/4 wave verticals with radials that we were using. But they are no match for a yagi.

If you look at the typical 3 element yagi, the "driven" element is nothing more than a center fed dipole, the reflector and directors being parasitic elements.

So, if you have space limitations, try the vertical dipole. It works and will give you between 1.5 to 2 dB gain.

I have one of those old Shakespear Big Sitcks in the garage now just waiting to get on the air on 10/12 meters. That is one very good antenna. It is a 1/2 wave sleave dipole. I like that design so much that I am building a couple more of them for 2m and 70 cm out of aluminum tubing salvaged from a torn folding lawn chair. I am even thinking about trying to build one for mobile use with a tubing lower section and a stainless steel stinger for the top section to put on my motorcycle since it doesn't have a great ground plain.

If it wasn't for the size requirments I would build one each for 20m and 40m.

4805. 80 meter loop configuration Question

Yahoo group: ham-antennas (2008)
Date: 2008-05-08 14:48:02 UTC
From: Jason
Topic: 4805 Message: 4805

Hi All,

I'm installing a 80 meter loop at my new house and running to a problem. Hopefully someone can help out.

Here are the details:

I was wondering if I could pick your brain on the 80m loop antenna I am installing at my new house. Here are the particulars that I posted on a Yahoo Group trying to gather information:

a) 272' of stranded 12 gauge wire in a relatively rectangular shape.

b) Van Gorden Antenna Center Insulator connects the 12 gauge wire in a tree.

c) 450 OHM 14GA Van Gorden Ladderline connects to my Insulator on one end and connects to a HI-Q 4:1 Balun on the other end.

d) From the 4:1 Balun a coax run goes into my shack on a Kenwood TS480SAT rig. (auto tuner)

I can tune just fine on 10, 15, 20, 40 meters! (even 160 and 6 meters tune at certain locations) Audio and SWR are perfect.

However, I cannot tune any higher than 3.800 on 75/80 meters. I have cut down the ladder line and no change. When I cut down the ladder line I tuned in the other bands perfectly. Ladder line sits at about 93 feet in length now. I tried cutting down further and I ended up taking out all the bands, so I reached the limit I believe. I put back the last piece I cut and now back to where I was.

I thought maybe the hardware store made a mistake and my 12 gauge wire was short. So I added 25 feet to it in the middle. It actually made 75/80 meters worse, as it didn't want to tune above 3.700. So I reverted back.

Any thoughts on what is happening? I seem to be stuck at 3.800. I don't know if this frequency, exactly, is telling me something? Any suggestions would be greatly appreciated!

Hello Bill,
I use a ladder for legal limit talk and I hove found that a twist
Evey couple of feet will keep the 'fluttering' in the wind down.
Also the use of a air-choke is almost a necessity. And 2 feet is in
IMHO more like 6 inches.

Mileage will vary of course!

Try a different tuner. Or place capacitor or inductor across the line at the read of the tuner.

Just out of interest guys I run a Antron 99 on 20m up to 10meters. It works great I use a MFJ 993B Auti intelituner to tun it down but my FWD & REF power are very good on this bands. My Double size G5RV is no good after 20m up so the antron 99 is tops for them bands. OH SCREW THE RINGS TO THE BOTTOM..... Just in case yo have one and wish to try...

Topic: 4790 Message: 4812

doing a bit of research, I find the Cushcraft Ringo was a 5/8 wave antenna, not 1/2 wave.
But is is a simple antenna. See:
<http://www.cushcraft.com/amateur/support/instruction-manuals.htm> and look at the AR10 and AR6 antennas (ten meters and six meters). they did redesign it a bit from the 11 meter version I had in the 70's. With a little ingenuity, it would not be too difficult to make a homebrew version.
Or maybe find one that you could get for little or nothing and resurrect it.
Mine had developed a high resistance leakage on the SO239 assembly. I could make a replacement of sorts for one that should work.
Easier to match than a half wave IMO. It uses a one turn coil, tapped via a rod, and the whole antenna is at ground potential, as long as the mount is grounded.

just looked in the newest HRO catalog, and they still sell the AR10 Ringo. Not sure what the price is though.

5/8 wave is just slightly longer than 1/2 wave = 4/8...

A similar antenna, though harder to make, would be a coaxial sleeve antenna. Mounting would also be harder. This uses a 1/4 wave whip and a 1/4 wave metal sleeve, fed inside the sleeve.

yesterday, I saw an antenna that I had not seen in years. Made by Avanti, I forget the model right now, but it acts similar to the coaxial sleeve.
I will do some searching later on and see if I can find a picrure of it.
They also made it in a 3 element beam configuration.
Most 11 meter antennas could be redone for 10 meters eaily enough, and maybe by adding a bit, would do for 12 meters as well...

Basic part of a 1/2 wave vertical antenna is a matching coil at the base, fed at a tap on the coil. But many made for 11 meters were using a 5/8 wave design, and maybe a few 3/4 wave.
Some of the older antenna books may have some info in them.
Not needing radials makes it easier to mount in many locations...
YMMV

Subject: [ham-antennas] Re: Half wave CB style verticals

I have one of those old Shakespear Big Sitcks in the garage now just waiting to get on the air on 10/12 meters. That is one very good antenna. It is a 1/2 wave sleave dipole. I like that design so much that I am building a couple more of them for 2m and 70 cm out of aluminum tubing salvaged from a torn folding lawn chair. I am even thinking about trying to build one for mobile use with a tubing lower section and a stainless steel stinger for the top section to put on my motorcycle since it doesn't have a great ground plain.

If it wasn't for the size requirments I would build one each for 20m and 40m.

4815. 450 ohm Ladderline lenght?

Yahoo group: ham-antennas (2008)
Date: 2008-05-09 19:26:28 UTC
From: Steve Hunt
Topic: 4815 Message: 4815

Hi guys,

I have another Q... this time about my Ladder line that runs from my Flattop Wire @ 55 feet hight to a 4:1 current Balun and then on 50' of 213 into my shack.

I have to move the wire antenna due to my Vertical that I put up or will put up. The Ladderline now is 100 feet in lenght and I want to extend it to apprx. 150' in lenght.

Can I extend the Ladderline without thought's? or should i extend my RG213 (which is harder to do, in my case...due to conduit work)?

Thanks for your input
best regards Steve W1CDX

My .02, extend the ladder line all the way to the outside wall of your shack, put the balun there and hack off all the extra coax so that the coax length to the tuner is as short as possible.

Most of your losses are incurred in your coax.

For a 135' wire, the 'magic' numbers for feed line length are multiples of 34.5' to help avoid harmonics on the ladder line.

Also, just curious, if that is a balanced feed point wire, equal lengths, why a 4:1 balun? Why not a 1:1...if in fact you are wide band tuning it with a manual tuner...sort of assuming that here.

4817. Moxon antenna

Yahoo group: ham-antennas (2008)
Date: 2008-05-09 20:16:36 UTC
From: swlstation
Topic: 4817 Message: 4817

Hello,

As a new amateur with limited space, i am looking for a small antenne, i read something about a
Moxon antenne, has anyone any field experience in the same situation i am, the situation is as
follows

1 small garden aprox 13 mtr long with some buildings in the garden (garden-house)
the hous is one in a row, so not a corner .
I have a telescopic mast (height approx 6 mtrs)
At the moment i am using a hombrew inverted vee, but this one is not good enough.

So if anyone has any experience, then pleasse tell me

Tanks for reading

Ron Snijders (PD 1 ANB)

4818. Re: [ham-antennas] 80 meter loop configuration Question

From: Wayne
Topic: 4805 Message: 4818

Based on what you have said, I would try removing about 10 feet of wire from the loop itself and see what you wind up with. Five feet on each side. maybe try another 10 feet if needed to get where you want.
With antennas, almost nothing is written in stone (but tons of theory on paper)...
of course, with each change, check on all bands.

What frequency?
I did use Moxon on 20 meters. From my experience it was not too directional.
Used bamboo poles. I guess you could call it "horizontal loop" configuration.
I was pretty easy to build with wire,fishing line and bamboo.
I would not use aluminum tubing for the elements, it could get too heavy.

Talked with a fellow on some island and he was very happy with it - but he was "DX" and on the beach!
As soon as I am done with my "portable 20 meter quad " I'll try Moxon again and let you know how it goes under present lousy propagation.
I think it could work in vertical configuration also.

yes, that's it exactly. Matter of fact, while looking at antennas online earlier, i found that same picture.
they also made a 3 element beam with the Astro Plane as the driven element.
Anyway, it was a fairly decent antenna, just required a bit more mast that some antennas of the day.

Hi Chris, and thanks for input

yes this is a balanced line and Joe who builds these "Cobras"
recommends a 4:1 Balun.

These are btw exceptionaly good Antenna's (see www.k1jek.com)

4822. Re: Half wave CB style verticals

Yahoo group: ham-antennas (2008)
Date: 2008-05-10 14:44:30 UTC
From: Keith
Topic: 4790 Message: 4822

The beam version was a 3 element called an Astrobeam.
It had tight little nulls on the back that could block out just about anything.
I had one in the 70's and it was a great little beam.
I was accused of ghost talking many times because I could hear and talk to barefoot mobiles 50-60 miles away on my stock 5 watt Realistic Mini 23, the other stations couldn't hear them.
The mast is a working part of the design so it doesn't interfere with the function of the antenna.

I'm talking on an original Avanti Astro-Plane now being my DC ground version of the Sigma was blown down in the storm.
The 5/8 wave works better than the Astro-Plane.

Keith

Could somebody please give some NEC data on this antenna?
It seems these "popular" "folded over" "antennas" need some theoretical backing.
Just keeping with the old timers - anything will radiate, but how efficiently - that is the question.

Vaclav AA7EJ

PS Back to building a quad!

A lot of people like them, they definitely intrigued me and I was considering making one of the cobra types and I found this information.

http://www.vk1od.net/cobra/index.htm

Basically, yes they work. Are they a miracle antenna? No. Are they an ideal over a resonant dipole? No. But they have a convenience factor to them similar to a Carolina Windom for all band use with an auto tuner.

From: Donal
Topic: 4826 Message: 4826

Please don't laugh... I'm new to messing with HF antennas and I really appreciate the help I've got from this group to now.

So I was wondering if it would be better to feed my 6BTV with some recycled ladderline salvaged from a G5RV (I know the feedline is in good condition as it was only installed for two weeks... one of the legs was damaged, so the antenna was replaced) I plan on running a shorter length of coax from the SO239 fitted to the ladderline? Would there be any benefits making this a worthy upgrade? Like less loss.

I'd appreciate any advice and once again much thanks for all the help and advice from the group to this point.

Ladder line is 300 or 450 ohm. I will bet that your BTV wants 50 ohm coax. If my assumption is true, you may have SWR problems by using ladder line..

Use of real open wire line, not ladder line or window line[anything covered with plastic] makes sense if you have a very long run to make[well over 100 feet]. Its use is shown in the older handbooks. a balun is required at each end to convert to 50 ohm coax . Otherwise use coax.

4831. Mobile HF antennas and related items FS

Yahoo group: ham-antennas (2008)
Date: 2008-05-11 17:11:28 UTC
From: Ken Simpson, W8EK
Topic: 4831 Message: 4831

Mobile HF antennas and antenna related items for sale:

Outbacker Perth HF Mobile antenna
The PERTH antenna covers 80-75-40-30-20-17-15-12-10m,
which means all of the HF bands, including the WARC bands.
The length is about 7 feet long (fully extended) with a 3 foot tip.
The Outbacker is constructed of fiberglass with pre-tuned copper
helical windings and covered with smooth epoxy-resin and a
coating of polyurethane for strength, and durability. The mounting
ferrule is nickel-plated brass with industry standard 3/8x24 threads.
Frequency coverage is broadband but the top of the antenna is
adjustable which allows tuning for the lowest possible VSWR even
on 75 meters and 10 meters. Tap points are clearly engraved for
each band. Changing bands is accomplished manually by plugging
the exclusive Outbacker "Wander Lead" into the proper tap.
The Outbacker antennas have a beautiful, shiny black finish.
This antenna works well and is in good shape. Included is a
package of "Penetrox" which should be used on the "Wander
Lead" to prevent corrosion, and make good contact. $250

Hamstick HF mobile antennas:

These are the original honest to goodness Hamsticks,
made by Lakeview, and are not one of the clones.

Each antenna, when fully assembled and tuned, is about
7 feet long, in a slim design that does not catch much wind.
Each has a 3/8 inch, 24 thread stud on the base, so they
fit a standard ball mount.

Two are available -- one for 20 meters and one for 40 meters.

These antennas are new, still in their original package, unused.

They are $30 each.

Hustler mobile antennas:

All work fine and are in good mechanical condition.

"Standard" Hustler resonators:
40 meter resonator RM-40 $17
20 meter resonator RM-20 $15
15 meter resonator RM-15 $14
10 meter resonator RM-10 $12

Hustler mobile masts:
MO-2 (folds about 27 inches above ball) $22

MO-1 mast that has a start of a split where it folds
.....over. It can be used as an MO-3 (non tilt mast)
.....or needs care when tilting. $ 15

RSS-2, Stainless steel resonator spring $10

MFJ 902 "Travel Tuner"
This HF tuner is small and compact, and is made to be
used with some of the new, small compact rigs, such as
the Icom 706, Yaesu FT-100, Kenwood TS-50, etc.,
although it will work fine with a larger fixed station rig.
It is designed for 80 thru 10 meter operation, and will
handle 150 watts.
It has provisions to bypass the tuner, if you so desire.
This particular unit works fine, and looks very close to new.
It is in its original box, with paper work. $65

Wattmeter/SWR Bridges:

Micronta 21-520 A wattmeter with large dual meters
This meter is designed primarily for HF operation, although
it still functions well on 6 and 2 meters. It has SO-239
connectors, and is designed for 52 ohm antenna systems.
